GIAMBELLI, PIERI, AND TABLEAU FORMULAS VIA RAISING OPERATORS

HARRY TAMVAKIS

Abstract. We give a direct proof of the equivalence between the Giambelli and Pieri type formulas for Hall-Littlewood functions using Young's raising operators, parallel to joint work with Buch and Kresch for the Schubert classes on isotropic Grassmannians. We prove several closely related mirror identities enjoyed by the Giambelli polynomials, which lead to new recursions for Schubert classes. The raising operator approach is applied to obtain tableau formulas for the Hall-Littlewood functions, the theta polynomials of [BKT2], and related Stanley symmetric functions. Finally, we introduce the notion of a skew element $w$ of the hyperoctahedral group and identify the set of reduced words for $w$ with the set of standard $k$-tableaux on a skew shape $\lambda/\mu$.

0. Introduction

The classical Schubert calculus is concerned with the algebraic structure of the cohomology ring of the Grassmannian $G(m, N)$ of $m$-dimensional subspaces of complex affine $N$-space. The cohomology has a free $\mathbb{Z}$-basis of Schubert classes $\sigma_\lambda$, induced by the natural decomposition of $G(m, N)$ into a disjoint union of Schubert cells. On the other hand, the ring is generated by the Chern classes of the universal quotient bundle $Q$ over $G(m, N)$, also known as the special Schubert classes. The theorems of Pieri [Pi] and Giambelli [G] are fundamental building blocks of the subject: the former is a rule for a product of a general Schubert class $\sigma_\lambda$ with a special one, while the latter is a formula equating $\sigma_\lambda$ with a polynomial in the special classes. When one expresses the Chern classes involved in terms of the Chern roots of $Q$, the Schubert classes are replaced by Schur $S$-polynomials, thus exhibiting a link between the Schubert calculus and the ring of symmetric functions.

In a series of papers with Buch and Kresch [BKT1, BKT2], we obtained corresponding results for the Grassmannians parametrizing (non-maximal) isotropic subspaces of a vector space equipped with a nondegenerate symmetric or skew-symmetric bilinear form. Our solution of the Giambelli problem for isotropic Grassmannians uses the raising operators of Young [Y] in an essential way; the resulting formula interpolates naturally between a Jacobi-Trudi determinant and a Schur Pfaffian. A rather different context in which a Giambelli type formula appears that has this interpolation property is the theory of Hall-Littlewood symmetric functions [Li, M]; these objects also satisfy a Pieri rule [Mo].

The raising operator approach allows one to see directly that the Pieri and Giambelli results are formally equivalent to each other in all the above instances. This amounts to showing that the Giambelli polynomials satisfy the Pieri rule, for the
converse implication then follows easily. As a consequence, working either in the
context of Schubert calculus or the theory of symmetric functions, it suffices to
prove either of the two theorems to establish them both. In geometry, the Pieri
rule may be proved concisely by studying a triple intersection of the appropriate
Schubert cells, following Hodge [H]; this is the method used in [BKT1].

When working algebraically, it is convenient to use the Giambelli formula as the
starting point, and this is the point of view of the present article. One advantage
of the raising operator definition is that it makes clear that the basic Giambelli
polynomials, which are indexed by partitions $\lambda$, make sense when the index is any
finite sequence of integers, positive or negative. When the index is a partition, it is
the axis of reflection for a pair of mirror identities, both closely connected to the
Pieri rule. The simplest example is in the case of Schur $S$-functions:

$$\sum_{\alpha \geq 0} s_{\lambda + \alpha} = \sum_{\mu \supset \lambda} s_{\mu} \quad \text{and} \quad \sum_{\alpha \geq 0} s_{\lambda - \alpha} = \sum_{\mu \subset \lambda} s_{\mu}$$

where the sums are over all compositions $\alpha$ and partitions $\mu$ obtained from $\lambda$ by
adding (respectively subtracting) a horizontal strip. In §4.4 we use raising operators
and the mirror identities to obtain top row recursion formulas for Schubert classes
on isotropic Grassmannians.

Our central thesis up to this point is that the aforementioned results may be
proved without recourse to their realizations in terms of symmetric functions. The
main application of the mirror identities, however, lies in the latter theory, where
they can be used to obtain reduction formulas for the number of variables $x$ which
appear in the argument of a symmetric polynomial. These in turn lead directly to
tableau formulas for the polynomials in question. The tableau formulas suggest
the introduction of new symmetric functions indexed by skew Young diagrams, and
one can then study their properties. In this way, many important aspects of the
classical theory of symmetric functions, as presented in the first three chapters of
[M], may be established by entirely different methods. Moreover, the intention is
to apply these techniques in a hitherto unexplored situation.

Our main result is a tableau formula for the theta polynomials of [BKT2], which
are the Billey-Haiman type C Schubert polynomials [BH] for Grassmannian ele-
ments of the hyperoctahedral group $B_\infty$ (the union of the Weyl groups for the root
systems of type $B_n$ or $C_n$). The theorem states that for any $k$-strict partition $\lambda$, we have

$$\Theta_\lambda(x; y) = \sum_U 2^{n(U)}(xy)^U$$

where the sum is over all $k$-bitableaux $U$ of shape $\lambda$ (see §5.3 for the precise defini-
tions). It bears emphasis that our proof of (1) does not use inner products, tableau
 correspondences, or algorithms such as jeu de taquin and the like. We show that
formula (1) (and its counterpart in the theory of Schur and Hall-Littlewood func-
tions) follows essentially from the definition of $\Theta_\lambda(x; y)$ using raising operators,
once the Pieri rule is established. The result is surprising because the Pieri rule for
the product $\varphi_p \cdot \Theta_\lambda$ involves partitions $\mu$ which do not contain the diagram of $\lambda$.

We are led to introduce symmetric functions $F_{\lambda/\mu}^{(k)}(x)$, defined for any pair $\mu \subset \lambda$
of $k$-strict partitions by the equation

$$F_{\lambda/\mu}^{(k)}(x) = \sum_T 2^{n(T)}x^T$$
where the sum is over all $k$-tableaux $T$ of skew shape $\lambda/\mu$. When $k = 0$, the $F^{(k)}_{\lambda/\mu}$ coincide with the usual skew Schur $Q$-functions $Q_{\lambda/\mu}$. For general $k$, we prove that $F^{(k)}_{\lambda/\mu}$ either vanishes or is equal to a certain type C Stanley symmetric function $F_w$, and therefore is always a nonnegative integer linear combination of Schur $Q$-functions. The function $F_w$ is indexed by an element $w$ of the hyperoctahedral group which we call skew. We argue that the skew elements of $B_\infty$ are directly analogous to the 321-avoiding permutations [BJS] in the symmetric group. For example, we show that the reduced words for $w$ are in 1-1 correspondence with the standard $k$-tableaux of shape $\lambda/\mu$.

We begin this article in §1 by giving a short proof using raising operators of the equivalence between the classical Giambelli formula and the Pieri rule. This is followed by a discussion of the analogous result for the algebra of Hall-Littlewood functions in §2, and then the more sophisticated arguments of [BKT2] in §3. The raising operators $R^\lambda$ which appear in the Giambelli formulas of isotropic Schubert calculus depend on the partition $\lambda$; this leads to a more challenging and dynamic theory. In §4 we obtain the mirror identities for Hall-Littlewood functions and isotropic Grassmannian Schubert classes, and give some first applications. Section 5 contains our treatment of the various tableau formulas. In §5.1 we stop short of proving the (known) tableau formula for skew Hall-Littlewood functions, since the more difficult case of theta polynomials and the skew functions $F^{(k)}_{\lambda/\mu}(x)$ is handled in detail in §5.2 – §5.5. Finally, in §6 we define the skew elements of the hyperoctahedral group and relate the results of §5 to the Billey-Haiman Schubert polynomials and type C Stanley symmetric functions.

For simplicity we will restrict to the type A and C theories throughout the article, and not discuss the analogous results for orthogonal Grassmannians and Weyl groups here. We hope that §1 and the examples of §3.2 provide a useful introduction to [BKT2]. To emphasize that the formulas in §1 - §4 do not depend on their specific realizations in the Schubert calculus or the theory of symmetric functions, we have used the nonstandard notation $U_\lambda$, $V_\lambda$, $W_\lambda$ for the basic polynomials, and in §1.4, §2.3, and §3.3 briefly discuss how these relate to other known objects.

Many thanks are due to my collaborators Anders Buch and Andrew Kresch for their inspired work on related projects.

1. The type A theory

1.1. Raising operators. An integer sequence or integer vector is a sequence of integers $\{\alpha_i\}_{i \geq 1}$, only finitely many of which are non-zero. The largest integer $\ell \geq 0$ such that $\alpha_\ell \neq 0$ is called the length of $\alpha$, denoted $\ell(\alpha)$; we will identify an integer sequence of length $\ell$ with the vector consisting of its first $\ell$ terms. We let $|\alpha| = \sum \alpha_i$ and $\# \alpha$ equal the number of non-zero parts $\alpha_i$ of $\alpha$. We write $\alpha \geq \beta$ if $\alpha_i \geq \beta_i$ for each $i$. An integer vector $\alpha$ is a composition if $\alpha_i \geq 0$ for all $i$ and a partition if $\alpha_i \geq \alpha_{i+1} \geq 0$ for all $i$. As is customary, we represent a partition $\lambda$ by its Young diagram of boxes, which has $\lambda_i$ boxes in row $i$. We write $\mu \subset \lambda$ instead of $\mu \leq \lambda$ for the containment relation between two Young diagrams; in this case the set-theoretic difference $\lambda \setminus \mu$ is called a skew diagram and denoted $\lambda/\mu$.

For two integer sequences $\alpha, \beta$ such that $|\alpha| = |\beta|$, we say that $\alpha$ dominates $\beta$ and write $\alpha \geq \beta$ if $\alpha_1 + \cdots + \alpha_i \geq \beta_1 + \cdots + \beta_i$ for each $i$. Given any integer
sequence \( \alpha = (\alpha_1, \alpha_2, \ldots) \) and \( i < j \), we define
\[
R_{ij}(\alpha) = (\alpha_1, \ldots, \alpha_i + 1, \ldots, \alpha_j - 1, \ldots);
\]
a raising operator \( R \) is any monomial in these \( R_{ij} \)'s. Note that we have \( R\alpha \succeq \alpha \) for any integer sequence \( \alpha \); conversely, if \( \alpha \succeq \beta \), there exists a raising operator \( R \) such that \( \alpha = R\beta \). See [M, I.1] for more information.

1.2. The Giambelli formula. Consider the polynomial ring \( A = \mathbb{Z}[u_1, u_2, \ldots] \) where the \( u_i \) are countably infinite commuting independent variables. We regard \( A \) as a graded ring with each \( u_i \) having graded degree \( i \), and adopt the convention here and throughout the paper that \( u_0 = 1 \) while \( u_r = 0 \) for \( r < 0 \). For each integer vector \( \alpha \), set \( u_\alpha = \prod_i u_{\alpha_i} \); then \( A \) has a free \( \mathbb{Z} \)-basis consisting of the monomials \( u_\lambda \) for all partitions \( \lambda \).

Given a raising operator \( R \), define \( Ru_\alpha = u_{R\alpha} \). Here we view the raising operator \( R \) as acting on the index \( \alpha \), and not on the monomial \( u_\alpha \) itself. Thus, if the components of \( \alpha \) are a permutation of the components of \( \beta \), it may happen that \( Ru_\alpha \neq Ru_\beta \) even though \( u_\alpha = u_\beta \) as elements of \( A \). Notice that if \( \alpha_\ell < 0 \) for \( \ell = \ell(\alpha) \), then \( Ru_\alpha = 0 \) in \( A \) for any raising operator \( R \).

For any integer vector \( \alpha \), define \( U_\alpha \) by the Giambelli formula
\[
U_\alpha := \prod_{i<j} (1 - R_{ij}) u_\alpha.
\]
Although the product in (2) is infinite, if we expand it into a series of terms we see that only finitely many of the summands are non-zero; hence, \( U_\alpha \) is well defined. For any partition \( \lambda \), we clearly have
\[
U_\lambda = u_\lambda + \sum_{\rho \succeq \lambda} a_{\lambda\rho} u_\rho
\]
where \( a_{\lambda\rho} \in \mathbb{Z} \) and the sum is over partitions \( \rho \) which strictly dominate \( \lambda \). We deduce that the \( U_\lambda \) for \( \lambda \) a partition form another \( \mathbb{Z} \)-basis of \( A \).

We have \( U_{(r,s)} = (1 - R_{12}) u_{(r,s)} = u_r u_s - u_{r+1} u_{s-1} \), hence \( U_{(r,s)} = -U_{(s-1, r+1)} \) for any \( r, s \in \mathbb{Z} \). This property has a straightforward generalization.

**Lemma 1.** Let \( \alpha \) and \( \beta \) be integer vectors. Then for any \( r, s \in \mathbb{Z} \) we have
\[
U_{(\alpha, r, s, \beta)} = -U_{(\alpha, s-1, r+1, \beta)}.
\]
We postpone the proof until §2, where we derive a more general result in the context of the Hall-Littlewood theory (Lemma 3).

1.3. The Pieri rule. For any \( d \geq 1 \) define the raising operator \( R^d \) by
\[
R^d = \prod_{1 \leq i < j \leq d} (1 - R_{ij}).
\]
For \( p > 0 \) and any partition \( \lambda \) of length \( \ell \), we compute
\[
u_p \cdot U_\lambda = u_p \cdot R^d u_\lambda = R^{\ell+1} \cdot \prod_{i=1}^{\ell} (1 - R_{i, \ell+1})^{-1} u_{(\lambda, p)} = R^{\ell+1} \cdot \prod_{i=1}^{\ell} (1 + R_{i, \ell+1} + R_{i, \ell+1}^2 + \cdots) u_{(\lambda, p)}
\]
and therefore
\[ u_p \cdot U_\lambda = \sum_{\nu \in \mathcal{N}} U_\nu, \]
where \( \mathcal{N} = \mathcal{N}(\lambda, p) \) is the set of all compositions \( \nu \geq \lambda \) such that \( |\nu| = |\lambda| + p \) and \( \nu_j = 0 \) for \( j > \ell + 1 \).

Call a composition \( \nu \in \mathcal{N} \) bad if there exists a \( j > 1 \) such that \( \nu_j > \lambda_j - 1 \), and let \( \mathcal{X} \) be the set of all bad compositions. Define an involution \( \iota : \mathcal{X} \to \mathcal{X} \) as follows: for \( \nu \in \mathcal{X} \), choose \( j \) maximal such that \( \nu_j > \lambda_j - 1 \), and set
\[ \iota(\nu) = (\nu_1, \ldots, \nu_{j-2}, \nu_j - 1, \nu_{j-1} + 1, \nu_{j+1}, \ldots, \nu_{\ell + 1}). \]

Lemma 1 implies that \( U_\nu + U_{\iota(\nu)} = 0 \) for every \( \nu \in \mathcal{X} \), therefore all bad indices may be omitted from the sum in (3). We are left with the Pieri rule
\[ u_p \cdot U_\lambda = \sum_{\nu} U_\nu \]
summed over all partitions \( \nu \) with \( |\nu| = |\lambda| + p \) such that \( \nu_1 \geq \lambda_1 \geq \nu_2 \geq \lambda_2 \geq \cdots \).

In the language of Young diagrams, this condition means that \( \nu \supset \lambda \) and the skew diagram \( \nu/\lambda \) is a horizontal \( p \)-strip.

Conversely, suppose that we are given a family \( \{ T_\lambda \} \) of elements of \( A \), one for each partition \( \lambda \), such that \( T_p = u_p \) for every integer \( p \geq 0 \) and the \( T_\lambda \) satisfy the Pieri rule \( T_p \cdot T_\lambda = \sum_{\nu} T_{\nu} \), with the sum over \( \nu \) as in (4). We claim then that
\[ T_\lambda = U_\lambda = \prod_{i<j} (1 - R_{ij}) u_\lambda \]
for every partition \( \lambda \). To see this, note that the Pieri rule implies that
\[ U_\lambda + \sum_{\mu > \lambda} a_{\lambda\mu} U_\mu = u_{\lambda_1} \cdots u_{\lambda_\ell} = T_\lambda + \sum_{\mu > \lambda} a_{\lambda\mu} T_\mu \]
for some constants \( a_{\lambda\mu} \in \mathbb{Z} \). The claim now follows by induction on \( \lambda \). We thus see that the Giambelli formula and Pieri rule are formally equivalent to each other.

### 1.4. The Grassmannian and symmetric functions.

Equation (2) may be written in the more familiar form
\[ U_\alpha = \det(u_{\alpha_i+j-i})_{1 \leq i,j \leq \ell}. \]

We will prove that (2) and (5) are equivalent, following [M, I.3]. Suppose the length of \( \alpha \) is \( \ell \) and let \( \rho = (0, 1, \ldots, \ell - 1) \). We work in the ring \( \mathbb{Z}[x_1, x_1^{-1}, \ldots, x_\ell, x_\ell^{-1}] \) and let \( Rx^\alpha = x^{R\alpha} \) for any raising operator \( R \). The key is to use the Vandermonde identity
\[ \det(x_j^{-1})_{1 \leq i,j \leq \ell} = \prod_{1 \leq i < j \leq \ell} (x_j - x_i) \]
which implies that
\[ \prod_{1 \leq i < j \leq \ell} (1 - R_{ij}) x^\alpha = \prod_{1 \leq i < j \leq \ell} (1 - x_i x_j^{-1}) x^\alpha = x^{\alpha - \rho} \det(x_j^{-1})_{1 \leq i,j \leq \ell} \]
\[ = \sum_{\sigma \in S_\ell} (-1)^{\sigma_1 + \sigma_1(1) - 1} \cdots x_{\ell+\sigma(\ell) - \ell} = \det(x_{i+j-i})_{1 \leq i,j \leq \ell}. \]

One now applies the \( \mathbb{Z} \)-module homomorphism \( \mathbb{Z}[x_1, x_1^{-1}, \ldots, x_\ell, x_\ell^{-1}] \to A \) sending \( x^\alpha \) to \( u_\alpha \) for each \( \alpha \) to both ends of the above equation to obtain the result.
The two standard realizations of the Pieri and Giambelli formulas in the literature are the cohomology ring of the Grassmannian $G = G(m,N)$ and the ring $A$ of symmetric functions. The ring $H^*(G,Z)$ has a free $Z$-basis of Schubert classes $\sigma_\lambda$, one for each partition $\lambda$ whose diagram is contained in an $m \times (N-m)$ rectangle $R(m,N-m)$. There is a ring epimorphism $\phi : A \to H^*(G,Z)$ sending the generators $u_p$ to the special Schubert classes $\sigma_p$ for $1 \leq p \leq N-m$ and to zero for $p > N-m$. The map $\phi$ satisfies $\phi(U_\lambda) = \sigma_\lambda$ if $\lambda \subset R(m,N-m)$, and $\phi(U_\lambda) = 0$ otherwise. For further details, the reader may consult e.g. [F, Chapter 9.4].

Let $x = (x_1, x_2, \ldots)$ be an infinite set of commuting variables, and for each $p \geq 0$ let $h_p = h_p(x)$ be the $p$-th complete symmetric function, that is, formal sum of all monomials in the $x_i$ of degree $p$. The ring $\Lambda = Z[h_1, h_2, \ldots]$ may be identified with the ring of symmetric functions in the variables $x_i$. There is a ring isomorphism $A \to \Lambda$ sending $u_p$ to $h_p$ for all $p$. For any partition $\lambda$, the element $U_\lambda$ is mapped to the Schur $S$-function $s_\lambda(x)$. The equation

$$s_\lambda(x) = \det(h_{\lambda+|\gamma|-j}(x))_{1 \leq i,j \leq \ell(\lambda)}$$

expressing the Schur functions in terms of the complete symmetric functions is called the Jacobi-Trudi identity (see e.g. [M, I.(3.4)]).

2. The Hall-Littlewood theory

2.1. The Giambelli formula. Let $v_1, v_2, \ldots$ be an infinite family of commuting variables, with $v_i$ having degree $i$ for all $i$. As before let $v_0 = 1$, $v_r = 0$ for $r < 0$, $v_\alpha = \prod_i v_{\alpha_i}$ for each integer sequence $\alpha$, and $R v_\alpha = v_{R\alpha}$ for any raising operator $R$. Let $t$ be a formal variable and consider the graded polynomial ring $A_t = Z[t][v_1, v_2, \ldots]$. For any integer vector $\alpha$, define $V_\alpha \in A_t$ by the Giambelli formula

$$V_\alpha := \prod_{i<j} \frac{1 - R_{ij}}{1 - t R_{ij}} v_\alpha.$$ (6)

Let $\alpha = (\alpha_1, \ldots, \alpha_{t-1})$ be an arbitrary integer vector and $r \in Z$. Expanding the raising operator product in (6)

$$\prod_{1 \leq i < j \leq t} \frac{1 - R_{ij}}{1 - t R_{ij}} = \prod_{1 \leq i < j < \ell} \frac{1 - R_{ij}}{1 - t R_{ij}} \prod_{i=1}^{t-1} \frac{1 - R_{i\ell}}{1 - t R_{i\ell}}$$

along the last (i.e., the $\ell$-th) component of $(\alpha, r)$ gives

$$V_{(\alpha, r)} = \sum_{\gamma} t_{\gamma}^{\ell} \sum_{i=1}^{t-1} \frac{1}{1 - \gamma_i} V_{\alpha+\gamma} v_r^{|\gamma|},$$ (7)

summed over all compositions $\gamma \in N^{t-1}$, where $N = \{0,1,\ldots\}$. Equation (7) may be used to give a recursive definition of $V_\alpha$. The $v_\lambda$ and $V_\lambda$ for $\lambda$ a partition form two free $Z[t]$-bases of $A_t$.

**Proposition 1.** Suppose that we have an equation in $A_t$

$$\sum_\nu a_\nu V_\nu = \sum_\nu b_\nu V_\nu$$

for some $a_\nu, b_\nu \in Z$. Then $V_\alpha$ is a basis of $A_t$, and any $V_\lambda$ basis of $A_t$.
where the sums are over all integer vectors \( \nu = (\nu_1, \ldots, \nu_\ell) \), while \( a_\nu \) and \( b_\nu \) are polynomials in \( \mathbb{Z}[t] \), only finitely many of which are non-zero. Then we have
\[
\sum_\nu a_\nu V_{(\mu, \nu)} = \sum_\nu b_\nu V_{(\mu, \nu)}
\]
for any integer vectors \( \mu \).

**Proof.** It suffices to show that if \( \sum_\nu c_\nu V_\nu = 0 \) for some \( c_\nu \in \mathbb{Z}[t] \), then \( \sum_\nu c_\nu V_{(\mu, \nu)} = 0 \). We will prove that \( \sum_\nu c_\nu V_{(\mu, \nu)} = 0 \) for any integer \( \nu \); the desired result then follows by induction.

Upon expanding the raising operators in the definition of \( V_\nu \), the equation \( \sum_\nu c_\nu V_\nu = 0 \) becomes \( \sum_\alpha \tilde{c}_\alpha v_\alpha = 0 \) for some coefficients \( \tilde{c}_\alpha \in \mathbb{Z}[t] \). Therefore must show that \( \sum_\alpha \tilde{c}_\alpha \Psi v_{(\nu, \alpha)} = 0 \), where \( \Psi = \prod_{j=2}^{\ell+1} \frac{1 - R_{1,j}}{1 - tR_{1,j}} \). For any integer sequence \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) and every permutation \( \tau \) in the symmetric group \( S_\ell \), define \( \tau(\alpha) = (\alpha_{\tau(1)}, \ldots, \alpha_{\tau(\ell)}) \). By exchanging rows, we may assume that \( \sum_\alpha \tilde{c}_\alpha v_\alpha \) and \( \sum_\alpha \tilde{c}_\alpha \Psi v_{(\nu, \alpha)} \) are both summed over decreasing integer sequences \( \alpha \), because
\[
\Psi v_{(\nu, \alpha)} = \sum_{\gamma \geq 0} t^{g|\gamma|} \frac{1}{\#(1 - 1)^\gamma} v_{p+|\gamma|} v_\alpha - \gamma = \Psi v_{(\nu, \tau(\alpha))}
\]
for every \( \tau \in S_\ell \). If \( \alpha \) has a negative component then clearly \( v_\alpha = \Psi v_{(\nu, \alpha)} = 0 \). Moreover, since the \( v_\alpha \) for \( \alpha \) a partition form a \( \mathbb{Z}[t] \)-basis of \( A_\ell \), it follows from \( \sum_\alpha \tilde{c}_\alpha v_\alpha = 0 \) that \( \tilde{c}_\alpha = 0 \) for all partitions \( \alpha \). We therefore have \( \sum_\alpha \tilde{c}_\alpha \Psi v_{(\nu, \alpha)} = 0 \), as desired. \( \square \)

For any integers \( r \) and \( s \), we claim that the equation
\[
(8) \quad V_{(r,s)} + V_{(s-1,r+1)} = t V_{(r+1,s-1)} + V_{(s,r)}
\]
holds in the ring \( A_\ell \). Indeed, (8) follows from the identity
\[
\frac{1 - R_{12}}{1 - tR_{12}} = (1 - R_{12}) + t \frac{1 - R_{12}}{1 - tR_{12}} R_{12}
\]
and the fact that \( (1 - R_{12})(v_{(r,s)} + v_{(s-1,r+1)}) = 0 \) in \( A_\ell \).

**Lemma 2.** For \( c \in \mathbb{Z} \) and \( d \geq 1 \), we have
\[
(9) \quad V_{(c,c+d)} + (1 - t) \sum_{i=1}^{d-1} V_{(c+i,c+d-i)} = t V_{(c+d,c)} .
\]

**Proof.** We use induction on \( d \). When \( d = 1 \) the result follows by setting \( s = r + 1 \) in (8). If \( d > 1 \), the inductive hypothesis gives
\[
(1 - t) \sum_{i=1}^{d-1} V_{(c+i,c+d-i)} = V_{(c+d-1,c+1)} - t V_{(c+1,c+d-1)} .
\]
The identity (9) thus reduces to
\[
V_{(c,c+d)} + V_{(c+d-1,c+1)} - t V_{(c+1,c+d-1)} = t V_{(c+d,c)} ,
\]
and this follows directly from equation (8). \( \square \)

We can generalize the identity (8) as follows.
Lemma 3. Let $\alpha$ and $\beta$ be integer vectors. Then for any $r, s \in \mathbb{Z}$ we have
\begin{equation}
V(\alpha, r, s, \beta) + V(\alpha, s - 1, r + 1, \beta) = t \left( V(\alpha, r + 1, s - 1, \beta) + V(\alpha, s, r, \beta) \right)
\end{equation}
in the ring $A_t$.

Proof. By Proposition 1, we may assume that $\alpha$ is empty. If $\beta = (\beta', b)$ has positive length, where $b \in \mathbb{Z}$, we set $\mu = (r, s, \beta')$ and the identity follows by induction, since
\[ V(\mu, b) = \sum_{\gamma} t^{\gamma - \# \gamma} (t - 1)^{\# \gamma} v_{\mu + \gamma} v_{b - \gamma}. \]
Finally, if both $\alpha$ and $\beta$ are empty, the result is true by (8). \qed

Notice that Lemma 1 is the specialization of Lemma 3 at $t = 0$. Using Lemma 3 with $\alpha = \emptyset$ and arguing as in the proof of Lemma 2 gives the following result.

Corollary 1. For $c \in \mathbb{Z}$, $d \geq 1$, and $\beta$ any integer vector, we have
\begin{equation}
V(c, c + d, \beta) + (1 - t) \sum_{i=1}^{d-1} V(c + i, c + d - i, \beta) = t V(c + d, c, \beta).
\end{equation}

2.2. The Pieri rule. Let $\lambda \subset \mu$ be two partitions such that $\mu/\lambda$ is a horizontal strip, and let $J$ be the set of integers $c \geq 1$ such that $\mu/\lambda$ does not (respectively does) have a box in column $c$ (respectively column $c + 1$). Define
\[ \psi_{\mu/\lambda}(t) = \prod_{c \in J} (1 - t^{m_c(\lambda)}), \]
where $m_c(\lambda)$ denotes the number of parts of $\lambda$ that are equal to $c$.

For any $d \geq 1$ define the raising operator $R^d_t$ by
\[ R^d_t = \prod_{1 \leq i < j \leq d} \frac{1 - R_{ij}}{1 - t R_{ij}}. \]

Given a partition $\lambda$ of length $\ell$, we compute
\begin{align*}
\nu_p \cdot V_\lambda &= \nu_p \cdot R^\ell_t v_\lambda = R^{\ell+1}_t \cdot \prod_{i=1}^\ell \frac{1 - t R_{i,\ell+1}}{1 - R_{i,\ell+1}} v_{(\lambda,p)} \\
&= R^{\ell+1}_t \cdot \prod_{i=1}^\ell (1 + (1 - t)R_{i,\ell+1} + (1 - t)R^2_{i,\ell+1} + \cdots) v_{(\lambda,p)}
\end{align*}
and therefore
\begin{equation}
\nu_p \cdot V_\lambda = \sum_{\nu \in \mathcal{N}} (1 - t)^{\#(\nu - \lambda)} V_\nu,
\end{equation}
where $\mathcal{N} = \mathcal{N}(\lambda, p)$ is the set of compositions $\nu \geq \lambda$ such that $|\nu| = |\lambda| + p$ and $\nu_j = 0$ for $j > \ell + 1$, as in §1.3.

For any integer composition $\nu$, set $\nu^* = (\nu_2, \nu_3, \ldots)$. Define
\[ \mathcal{N}^* = \{ \nu \in \mathcal{N} \mid \nu_j \leq \lambda_{j-1} \text{ for } j > 2 \} \]
and for $\nu \in \mathcal{N}^*$, let
\[ T_\nu = (1 - t)^{\#(\nu_1 - \lambda_1)} \psi_{\nu^*/\lambda^*}(t) V_\nu. \]

Using Proposition 1 and induction on the length of $\lambda$ gives
\begin{equation}
\sum_{\nu \in \mathcal{N}} (1 - t)^{\#(\nu - \lambda)} V_\nu = \sum_{\nu \in \mathcal{N}^*} T_\nu.
\end{equation}
Note that if \( \nu \in \mathbb{N}^* \) satisfies \( \nu_2 < \lambda_1 \), then \( T_{\nu} = \psi_{\nu/\lambda}(t) V_{\nu} \). Therefore
\[
\sum_{\nu \in \mathbb{N}^*} T_{\nu} = \sum_{\nu \in \mathbb{N}^*} \psi_{\nu/\lambda}(t) V_{\nu} + \sum_{\nu \in \mathbb{N}^*} T_{\nu}.
\]
We claim that for each fixed \( d \geq 0 \),
\[
\sum_{\nu \in \mathbb{N}^*} T_{\nu} = \sum_{\nu \in \mathbb{N}^*} \psi_{\nu/\lambda}(t) V_{\nu}.
\]
Equation (14) is justified by using Corollary 1 to fix all rows except the first two. We then apply the identity
\[
V(c, c+d) + (1-t) \sum_{i=1}^{d-1} V(c+i, c+d-i) + (1-t) V(c+d, c) = V(c+d, c)
\]
when \( \nu \setminus \lambda \) has a box in column \( c = \lambda_1 \), and the identity
\[
(1-t^m) V(c, c+d) + (1-t)(1-t^m) \sum_{i=1}^{d-1} V(c+i, c+d-i) + (1-t) V(c+d, c) = (1-t^{m+1}) V(c+d, c)
\]
for \( m \geq 1 \), otherwise. The identities (15) and (16) follow directly from Lemma 2, proving the claim.

Summing (14) over all \( d \geq 0 \), applying the result to (13), and taking (11) and (12) into account, we finally obtain the Pieri rule
\[
v_p \cdot V_\lambda = \sum_{\mu} \psi_{\mu/\lambda}(t) V_{\mu},
\]
summed over all partitions \( \mu \supset \lambda \) with \( |\mu| = |\lambda| + p \) and \( \mu/\lambda \) a horizontal \( p \)-strip.

Conversely, suppose that we are given a family \( \{T_\lambda\} \) of elements of \( A_t \), one for each partition \( \lambda \), such that \( T_p = v_p \) for every integer \( p \geq 0 \) and the \( T_\lambda \) satisfy the Pieri rule \( T_p \cdot T_\lambda = \sum_{\mu} \psi_{\mu/\lambda}(t) T_{\mu} \), with the sum over \( \mu \) and \( \psi_{\mu/\lambda}(t) \) as in (17). It follows then as in §1.3 that
\[
T_\lambda = V_\lambda = \prod_{i<j} \frac{1-R_{ij}}{1-tR_{ij}} v_\lambda.
\]
We have established that the Giambelli formula (6) and Pieri rule (17) are formally equivalent to each other.

2.3. Hall-Littlewood symmetric functions. Let \( x = (x_1, x_2, \ldots) \) be as in §1.4, define the formal power series \( q_r(x; t) \) by the generating equation
\[
\prod_{i=1}^{\infty} \frac{1-x_i t^2}{1-x_i z} = \sum_{r=0}^{\infty} q_r(x; t) z^r
\]
and set \( \Gamma_t = \mathbb{Z}[t][q_1, q_2, \ldots] \). There is a \( \mathbb{Z}[t] \)-linear ring isomorphism \( A_t \to \Gamma_t \) sending \( v_r \) to \( q_r(x; t) \) for all \( r \geq 1 \). For any partition \( \lambda \), the element \( V_\lambda \) is mapped to the Hall-Littlewood function \( Q_\lambda(x; t) \). The raising operator formula (6) for Hall-Littlewood functions is due to Littlewood [Li], who also obtained Lemma 3 in this setting. The Pieri rule (17) for the functions \( Q_\lambda(x; t) \) was first proved by Morris [Mo]; an alternative proof may be found in [M, III.5].
3. The Type C Theory: Isotropic Grassmannians

3.1. The Giambelli Formula. We consider an infinite family \( w_1, w_2, \ldots \) of commuting variables, with \( w_i \) of degree \( i \) for all \( i \), and set \( w_0 = 1, w_r = 0 \) for \( r < 0 \), and \( w_\alpha = \prod_i w_{\alpha_i} \) as before. Let \( I^{(k)} \subset \mathbb{Z}[w_1, w_2, \ldots] \) be the ideal generated by the relations

\[
1 - \frac{R_{12}}{1 + R_{12}} w_{(r,r)} = w_r^2 + 2 \sum_{i=1}^{r} (-1)^i w_{r+i} w_{r-i} = 0 \quad \text{for } r > k.
\]

Define the graded ring \( B^{(k)} = \mathbb{Z}[w_1, w_2, \ldots]/I^{(k)} \). All equations in \( B^{(k)} \), such as the Giambelli and Pieri formulas, will be valid only up to the elements of \( I^{(k)} \).

Let \( \Delta^0 = \{ (i,j) \in \mathbb{N} \times \mathbb{N} \mid 1 \leq i < j \} \), equipped with the partial order \( \leq \) defined by \( (i',j') \leq (i,j) \) if and only if \( i' \leq i \) and \( j' \leq j \). A finite subset \( D \) of \( \Delta^0 \) is a valid set of pairs if it is an order ideal, i.e., \( (i,j) \in D \) implies \( (i',j') \in D \) for all \( (i',j') \in \Delta^0 \) with \( (i',j') \leq (i,j) \).

A partition \( \lambda \) is \( k \)-strict if all its parts greater than \( k \) are distinct. Given a \( k \)-strict partition \( \lambda \), we define a set of pairs \( \mathcal{C}(\lambda) \) by

\[
\mathcal{C}(\lambda) = \{ (i,j) \in \Delta^0 \mid \lambda_i + \lambda_j > 2k + j - i \text{ and } j \leq \ell(\lambda) \}.
\]

It is easy to check that \( \mathcal{C}(\lambda) \) is a valid set of pairs. Conversely, assuming \( k > 0 \), let \( D \) be any valid set of pairs and set \( d_i = \# \{ j \mid (i,j) \in D \} \). Then the prescription

\[
\lambda_i = \begin{cases} k + 1 + d_i & \text{if } d_i > 0, \\ k & \text{if } d_i = 0 \end{cases}
\]

for \( 1 \leq i \leq d_1 + 1 \) defines a \( k \)-strict partition \( \lambda \) such that \( \mathcal{C}(\lambda) = D \). The white dots in Figure 1 illustrate a typical valid set of pairs.

For any valid set of pairs \( D \), we define the raising operator

\[
R^D = \prod_{i<j} (1 - R_{ij}) \prod_{i<j: (i,j) \in D} (1 + R_{ij})^{-1}.
\]

If \( \lambda \) is a \( k \)-strict partition, then set \( R^\lambda := R^{C(\lambda)} \). For any such \( \lambda \), define \( W_\lambda \in B^{(k)} \) by the Giambelli formula

\[
W_\lambda := R^\lambda w_\lambda.
\]
In contrast to (2) and (6), we see that the raising operator $R_\lambda$ in the Giambelli definition (19) depends on $\lambda$. When $\lambda_i + \lambda_j \leq 2k + j - i$ for all $i < j$, equation (19) becomes $W_\lambda = \prod_{i<j} (1-R_{ij}) w_\lambda$, while when $\lambda_i + \lambda_j > 2k + j - i$ for $1 \leq i < j \leq \ell(\lambda)$, the formula is equivalent to $W_\lambda = \prod_{i<j} 1 - R_{ij} w_\lambda$.

**Example 1.** In the ring $B^{(2)}$ we have

\[
W_{621} = \frac{1 - R_{12} 1 - R_{13}}{1 + R_{12} 1 + R_{13}} (1 - R_{23}) w_{621}
= (1 - 2R_{12} + 2R_{12}^2 - \cdots)(1 - 2R_{13} + 2R_{13}^2 - \cdots)(1 - R_{23}) w_{621}
= (1 - 2R_{12} + 2R_{12}^2 - 2R_{12}^3)(1 - 2R_{13} - R_{23}) w_{621}
= w_{621} - w_{63} - 2w_{711} + 4w_{81} - 2w_9
= w_6 w_2 w_1 - w_6 w_3 - 2w_7 w_2^2 + 4w_8 w_1 - 2w_9.
\]

From equation (18) we deduce that either the partition $\lambda$ is $k$-strict, or $w_\lambda$ is a $\mathbb{Z}$-linear combination of the $w_\mu$ such that $\mu$ is $k$-strict and $\mu \succ \lambda$. It follows that the $w_\lambda$ for $\lambda$ $k$-strict span $B^{(k)}$ as an abelian group. A dimension counting argument shows that in fact, the $w_\lambda$ for $\lambda$ $k$-strict form a $\mathbb{Z}$-basis of $B^{(k)}$. From the definition (6) it follows that for any partition $\lambda$, $W_\lambda$ is of the form

\[
W_\lambda = w_\lambda + \sum_{\mu \succ \lambda} a_{\lambda \mu} w_\mu
\]

with coefficients $a_{\lambda \mu} \in \mathbb{Z}$. We deduce that

\[
W_\lambda = w_\lambda + \sum_{\mu \succ \lambda} b_{\lambda \mu} w_\mu
\]

with the sum restricted to $k$-strict partitions $\mu \succ \lambda$. Therefore, the $W_\lambda$ as $\lambda$ runs over $k$-strict partitions form a $\mathbb{Z}$-basis of $B^{(k)}$.

More generally, given a valid set of pairs $D$ and an integer sequence $\alpha$, we denote $R^D w_\alpha$ by $W^D_{\alpha}$. We say that $D$ is the denominator set of $W^D_{\alpha}$. If $r, s \in \mathbb{Z}$, then

\[
W^D_{(r,s)} = -W^D_{(s-1,r+1)}
\]

while if $D \neq \emptyset$ and $r + s > 2k$, then

\[
W^D_{(r,s)} = -W^D_{(s,r)}
\]

in the ring $B^{(k)}$. To generalize these equations, care is required, as e.g. the direct analogue of Lemma 1 for the $W^D_{\alpha}$ fails. Suppose $D$ is a valid set of pairs and $j \geq 1$. We say that the pair $(j, j + 1)$ is $D$-tame if

---

**Figure 1.** A set of pairs (in white) and its outside rim (in grey).
Figure 2. Two $k$-related boxes in a $k$-strict Young diagram

(i) $(j, j + 1) \not\in D$ and for all $h < j$, $(h, j) \not\in D$ if and only if $(h, j + 1) \not\in D$, or
(ii) $(j, j + 1) \in D$ and for all $h > j + 1$, $(j, h) \in D$ if and only if $(j + 1, h) \in D$.

Lemma 4 ([BKT2]). Let $\alpha = (\alpha_1, \ldots, \alpha_{j-1})$ and $\beta = (\beta_{j+2}, \ldots, \beta_k)$ be integer vectors, and assume that $(j, j + 1)$ is $D$-tame.

(a) If $(j, j + 1) \not\in D$, then for any $r, s \in \mathbb{Z}$ we have
$$W_D^{(\alpha, r, s, \beta)} = -W_D^{(\alpha, s-1, r+1, \beta)}.$$  
(b) If $(j, j + 1) \in D$, then for any $r, s \in \mathbb{Z}$ such that $r + s > 2k$, we have
$$W_D^{(\alpha, r, s, \beta)} = -W_D^{(\alpha, s, r, \beta)}.$$

Example 2. The ring $B := B^{(0)}$ has free $\mathbb{Z}$-basis consisting of the $W_\lambda$ for $\lambda$ a strict partition, and the Giambelli formula (19) is equivalent to the identity

$$W_\lambda = \prod_{i<j} \frac{1 - R_{ij}}{1 + R_{ij}} w_\lambda.$$  

Lemma 4 in this case gives $W_{(\alpha, r, s, \beta)} = -W_{(\alpha, s, r, \beta)}$ whenever $r + s > 0$.

3.2. The Pieri rule. We begin our analysis in the same way as in the previous sections. For $p > 0$ and any $k$-strict partition $\lambda$ of length $\ell$, we find that

$$w_p \cdot W_\lambda = \sum_{\nu \in \mathcal{N}} W_\nu^{C(\lambda)},$$

where $\mathcal{N} = \mathcal{N}(\lambda, p)$ is the set of all compositions $\nu \geq \lambda$ such that $|\nu| = |\lambda| + p$ and $\nu_j = 0$ for $j > \ell + 1$. The problem with the right hand side of (21) is two-fold: first, the compositions $\nu \in \mathcal{N}$ are not $k$-strict partitions, and second, the denominator set $C(\lambda)$ is the same for each term in the sum, and will have to be modified so as to agree with the summands in the eventual Pieri rule. Rather than give the complete argument, we will state the Pieri rule which results and then discuss some features of the proof.

We let $[r, c]$ denote the box in row $r$ and column $c$ of a Young diagram. Suppose that $c \leq k < c'$. We say that the boxes $[r, c]$ and $[r', c']$ are $k$-related if $c + c' = 2k + 2 + r - r'$. In the diagram of Figure 2, the two grey boxes are $k$-related.

Given two partitions $\lambda$ and $\mu$ with $\lambda \subset \mu$, the skew Young diagram $\mu/\lambda$ is called a vertical strip if it does not contain two boxes in the same row. For any two $k$-strict partitions $\lambda$ and $\mu$, let $\alpha_i$ (respectively $\beta_i$) denote the number of boxes of $\lambda$ (respectively $\mu$) in column $i$, for $1 \leq i \leq k$. We have a relation $\lambda \rightarrow \mu$ if $\mu$ can be
obtained by removing a vertical strip from the first \( k \) columns of \( \lambda \) and adding a horizontal strip to the result, so that for each \( i \) with \( 1 \leq i \leq k \),

(1) if \( \beta_i = \alpha_i \), then the box \([\alpha_i, i] \) is \( k \)-related to at most one box of \( \mu \setminus \lambda \); and

(2) if \( \beta_i < \alpha_i \), then the boxes \([\beta_i, i], \ldots, [\alpha_i, i] \) must each be \( k \)-related to exactly one box of \( \mu \setminus \lambda \), and these boxes of \( \mu \setminus \lambda \) must all lie in the same row.

If \( \lambda \rightarrow \mu \), we let \( \Lambda \) be the set of boxes of \( \mu \setminus \lambda \) in columns \( k + 1 \) and higher which are not mentioned in (1) or (2). Define the connected components of \( \Lambda \) by agreeing that two boxes in \( \Lambda \) are connected if they share at least a vertex. Then define \( N(\lambda, \mu) \) to be the number of connected components of \( \Lambda \) which do not have a box in column \( k + 1 \). Finally, we can state the Pieri rule for \( B^{(k)} \): Given any \( k \)-strict partition \( \lambda \) and integer \( p \geq 0 \),

\[
(22) \quad w_p \cdot W_\lambda = \sum_{\substack{\lambda \rightarrow \mu \in \Delta^k \setminus \mathcal{C} \\ |\mu| = |\lambda| + p}} 2^{N(\lambda, \mu)} W_\mu.
\]

The outside rim \( \partial \mathcal{C} \) of \( \mathcal{C} = \mathcal{C}(\lambda) \) is the set of pairs \((i, j) \in \Delta^o \setminus \mathcal{C} \) such that \( i = 1 \) or \((i - 1, j - 1) \in \mathcal{C} \); an example of these sets is displayed in Figure 1. The Young diagrams of the partitions \( \mu \) which appear in (22) do not all contain the diagram of \( \lambda \), in contrast to the Pieri rule of \( \S 2.2 \) for Hall-Littlewood functions. However, the denominator sets \( \mathcal{C}(\mu) \) for the partitions \( \mu \) with \( \lambda \rightarrow \mu \) all contain \( \mathcal{C} \), are contained in \( \mathcal{C} \cup \partial \mathcal{C} \), and are empty beyond column \( \ell + 1 \).

To prove (22), our task is to show that

\[
(23) \quad \sum_{\nu \in N(\lambda, p)} W_\nu^{\mathcal{C}(\lambda)} = \sum_{\substack{\lambda \rightarrow \mu \in \Delta^k \setminus \mathcal{C} \\ |\mu| = |\lambda| + p}} 2^{N(\lambda, \mu)} W_\mu^{\mathcal{C}(\mu)}.
\]

It is clear that we need a mechanism to modify the denominator sets of the terms \( W_\nu^{\mathcal{C}(\lambda)} \) on the left hand side of (23). This is based on the observation that if \( D \) is a denominator set and \((i, j) \in \Delta^o \setminus D \), then

\[
(24) \quad W_\alpha^D = W_\alpha^{D \setminus (i,j)} + W_{R_{ij} \alpha}^{D \setminus (i,j)}.
\]

Equation (24) follows directly from the raising operator identity

\[
1 - R_{ij} = \frac{1 - R_{ij}}{1 + R_{ij}} + \frac{1 - R_{ij}}{1 + R_{ij}} R_{ij}.
\]

The following three detailed examples illustrate how Lemma 4 and (24) may be used repeatedly to obtain (23). For simplicity, the commas are omitted from the notation for integer vectors and pairs.

**Example 3.** The following chain of equalities holds in \( B^{(1)} \).

\[
w_1 \cdot W_{3211} = W_{3211}^{12} + W_{3212}^{12} + W_{3221}^{12} + W_{3311}^{12} + W_{4211}^{12}
\]

\[
= W_{3211}^{12} + (W_{3212}^{12, 13} + W_{3221}^{12, 13} + W_{4211}^{12, 13} + W_{5201}^{12, 13})
\]

\[
= W_{3211}^{12} + (W_{3221}^{12, 13, 23} + W_{3311}^{12, 13, 23}) + 2 W_{4211}^{12, 13} + (W_{5201}^{12, 13, 14} + W_{5201}^{12, 13, 14})
\]

\[
= W_{3211}^{C(3211)} + 2 W_{4211}^{C(4211)} + W_{62}^{C(62)}.
\]

Observe that Lemma 4(a) is used to show that \( W_{3212}^{12} = W_{5201}^{12, 13, 14} = 0 \), while Lemma 4(b) implies that \( W_{3311}^{12} = W_{3221}^{12} = W_{3311}^{12} = 0 \).
Example 4. The following chain of equalities holds in $B^{(1)}$.

$$w_3 \cdot W_{21} = W_{51}^3 + W_{42}^3 + W_{311}^3 + W_{33}^3 + W_{24}^3$$
$$+ W_{321}^3 + W_{312}^3 + W_{231}^3 + W_{222}^3 + W_{213}^3$$
$$= (W_{51}^{12} + W_{6}^{12}) + (W_{42}^{12} + W_{51}^{12}) + (W_{311}^{12} + W_{501}^{12}) + (W_{33}^{12} + W_{42}^{12})$$
$$+ (W_{24}^{12} + W_{33}^{12}) + (W_{321}^{12} + W_{411}^{12}) + (W_{231}^{12} + W_{321}^{12})$$
$$= W_6^{12} + 2W_{51}^{12} + W_{42}^{12} + (W_{411}^{12} + W_{51}^{12}) + (W_{311}^{12} + W_{51}^{12})$$
$$+ W_{321}^{12} + (W_{411}^{12} + W_{51}^{12})$$
$$= 2W_6^{C(0)} + 4W_5^{C(51)} + W_4^{C(42)} + 2W_4^{C(411)} + W_3^{C(321)}.$$

Here we use Lemma 4(a) to see that

$$W_{312}^3 = W_{222}^3 + W_{213}^3 = W_{501}^{12} = 0,$$

while Lemma 4(b) gives

$$W_{33}^{12} = W_{42}^{12} + W_{24}^{12} = W_{321}^{12} + W_{231}^{12} = 0.$$

Example 5. Let $k = 0$. We give a complete cancellation scheme along the above lines assuming that the integer $p$ is less than or equal to $\lambda$. For any integers $d, e \geq 1$ define the raising operator $R^{[d,e]}$ by

$$R^{[d,e]} = \prod_{1 \leq i < j \leq d} (1 - R_{ij}) \prod_{1 \leq i < j \leq e} (1 + R_{ij})^{-1}.$$

We compute that

$$w_p \cdot W_\lambda = R^{[\ell,\ell]} w_\lambda = \sum_{\nu \in \mathcal{N}'} R^{[\ell+1,\ell]} w_\nu = \sum_{\nu \in \mathcal{N}'} R^{[\ell+1,\ell+1]} \prod_{i=1}^{\ell}(1 + R_{i,\ell+1}) w_\nu$$

and therefore

$$(25) \quad w_p \cdot W_\lambda = \sum_{(\nu, \gamma) \in \mathcal{N}'(\lambda, p)} W_\nu \gamma$$

where $\mathcal{N}'(\lambda, p)$ denotes the set of all pairs $(\nu, \gamma)$ of integer vectors of length at most $\ell + 1$ with $\nu \in \mathcal{N}$, $\nu + \gamma \geq \lambda$, $|\nu + \gamma| = |\lambda| + p$, and $\gamma \in \{0, 1\}$ for $1 \leq i \leq \ell$.

For every pair $(\nu, \gamma) \in \mathcal{N}'(\lambda, p)$, define $\mu = \nu + \gamma$. Call a pair $(\nu, \gamma)$ bad if there exists a $j > 1$ such that

(i) $\mu_j = \mu_{j-1}$ or (ii) $\mu_j > \lambda_{j-1}$ or (iii) $\mu_j = \lambda_{j-1}$ and $\gamma_j = 0$.

Let $X$ be the set of all bad pairs in $\mathcal{N}'(\lambda, p)$. We next define an involution $\iota : X \rightarrow X$ as follows. For $(\nu, \gamma) \in X$, choose $j$ maximal such that (i), (ii), or (iii) holds. If $\mu_j = \mu_{j-1}$, we let $(\nu', \gamma') = (\nu, \gamma)$. Otherwise, let $\varpi \in S_\ell$ be the transposition $(j-1, j)$ and define $(\nu', \gamma')$ by setting $(\nu'_i, \gamma'_i) = (\nu_{\varpi(i)}, \gamma_{\varpi(i)})$ for $1 \leq i \leq \ell$. Finally, set $i(\nu, \gamma) = (\nu', \gamma')$ for each $(\nu, \gamma) \in X$. Lemma 4 applied to rows $j-1$ and $j$ gives $W_{\nu + \gamma} = -W_{\nu' + \gamma'}$ for every $(\nu, \gamma) \in X$, therefore all bad indices may be omitted from the sum in (25).

We are left with pairs $(\nu, \gamma)$ such that $\mu = \nu + \gamma \supset \lambda$ is a strict partition with $\mu/\lambda$ a horizontal strip. Observe that every connected component $C$ of $\mu/\lambda$ which does not lie in row $\ell + 1$ contributes a multiplicity of 2 to the sum (25). Indeed, if.
C lies in rows $r$ through $s$ with $r \leq s$, then condition (iii) implies that $\gamma_i = 1$ for $r < i \leq s$, while $\gamma_r$ can be either 0 or 1. We have therefore proved the Pieri rule
\[
w_p \cdot W_\lambda = \sum_{\mu} 2^{N(\lambda, \mu)} W_\mu
\]
summed over all strict partitions $\mu \supset \lambda$ with $|\mu| = |\lambda| + p$ and $\mu/\lambda$ a horizontal $p$-strip. The exponent $N(\lambda, \mu)$ equals the number of connected components of $\mu/\lambda$ which do not meet the first column.

In the general case, there is a substitution algorithm by which the left hand side of (23) evolves into the right hand side. Although Examples 3, 4, and 5 appear encouraging, they are still far from a precise formulation of this algorithm for a general Pieri product $w_p \cdot W_\lambda$. It is instructive to try to prove along these lines that the Pieri rule of Example 5 holds without the simplifying assumption that $p \leq \lambda_i$. The complete proof for arbitrary $k \geq 0$ is given in [BKT2]; we note here that for technical reasons, the argument is performed in type B, that is, for odd orthogonal Grassmannians. Each summand $W^C_\nu$ for $\nu \in \mathcal{N}$ in (23) gives rise to a tree of successor terms, with the branching given by repeated substitutions using (24). In this way, we obtain the substitution forest; the roots of the trees in the forest are the $W^C_\nu$ for $\nu \in \mathcal{N}$. By construction, the sum of all the roots is equal to the sum of all the leaves. When the algorithm terminates, the set of leaves contains the terms $W^C_\mu$ for $\lambda \to \mu$, each appearing exactly $2^{N(\lambda, \mu)}$ times; the remaining leaves are either zero or cancel in pairs, as dictated by Lemma 4.

Once we know that the Giambelli formula (19) used to define $W_\lambda$ satisfies the Pieri rule (22), the same reasoning as in the previous two sections establishes that the two results are formally equivalent.

### 3.3. The isotropic Grassmannian and theta polynomials

Let the vector space $E = \mathbb{C}^{2n}$ be equipped with a nondegenerate skew-symmetric bilinear form. A subspace $\Sigma$ of $E$ is isotropic if the form vanishes when restricted to $\Sigma$. The dimensions of such isotropic subspaces $\Sigma$ range from 0 to $n$; when $\dim(\Sigma) = n$ we say that $\Sigma$ is a Lagrangian subspace.

Choose $n \geq k \geq 0$ and let $\text{IG} = \text{IG}(n-k,2n)$ denote the Grassmannian parametrizing isotropic subspaces of $E$. Its cohomology ring $H^*(\text{IG}, \mathbb{Z})$ has a free $\mathbb{Z}$-basis of Schubert classes $\sigma_\lambda$, one for each $k$-strict partition $\lambda$ whose diagram is contained in the $(n-k) \times (n+k)$ rectangle $\mathcal{R}(n-k, n+k)$. Following [BKT1, BKT2], the special Schubert classes $\sigma_p$ for $\text{IG}$ are the Chern classes of the universal quotient bundle over $\text{IG}$, as in §1.4. There is a ring epimorphism $\psi: B^{(k)} \to H^*(\text{IG}, \mathbb{Z})$ sending the generators $w_p$ to the special Schubert classes $\sigma_p$ for $1 \leq p \leq n+k$ and to zero for $p > n+k$. For any $k$-strict partition $\lambda$, we have $\psi(W_\lambda) = \sigma_\lambda$ if $\lambda \subset \mathcal{R}(n-k, n+k)$, and $\psi(W_\lambda) = 0$ otherwise.

Let $x = (x_1, x_2, \ldots)$ as in §1.4 and set $y = (y_1, \ldots, y_k)$. Define the formal power series $\theta_r(x; y)$ by the generating equation
\[
\prod_{i=1}^\infty \frac{1 + x_i t}{1 - x_i t} \prod_{j=1}^k (1 + y_j t) = \sum_{r=0}^\infty \theta_r(x; y)t^r.
\]

Set $\Gamma^{(k)} = \mathbb{Z}[\theta_1, \theta_2, \ldots]$ to be the ring of theta polynomials. There is a ring isomorphism $B^{(k)} \to \Gamma^{(k)}$ sending $w_p$ to $\theta_p$ for all $p$. For any $k$-strict partition $\lambda$, the
element $W_\lambda$ is mapped to the \textit{theta polynomial} $\Theta_\lambda(x:y)$ of [BKT2]. These polynomials agree with the Schubert polynomials of type C defined by Billey and Haiman [BH] indexed by a Grassmannian permutation of the hyperoctahedral group; see [BKT2, §6] and §6 of the present paper for further information.

We next discuss this theory when $k = 0$. If $\alpha$ has length $\ell$ and $m > 0$ is the least integer such that $2m \geq \ell$, then equation (20) may be written in its original form

\begin{equation}
W_\alpha = \text{Pfaffian}(W_{\alpha_i, \alpha_j})_{1 \leq i < j \leq 2m}.
\end{equation}

To see this, one may argue as in §1.4, this time using Schur’s identity [S, §IX]

\[ \prod_{1 \leq r < s \leq 2m} x_r - x_s = \text{Pfaffian} \left( \frac{x_r - x_s}{x_r + x_s} \right)_{1 \leq r, s \leq 2m}. \]

In the theory of symmetric functions, the ring $\Gamma := \Gamma^{(0)}$ is called the ring of Schur $Q$-functions. For any strict partition $\lambda$, the element $W_\lambda$ is mapped to the Schur $Q$-function $Q_\lambda(x)$, which Schur [S] defined using the Pfaffian equation (26).

Let $\phi$ denote the ring homomorphism $A_{-1} \to \Gamma$ sending $v_p$ to $q_p(x)$ for every $p \geq 1$. Then $\phi(V_\lambda) = Q_\lambda(x)$ whenever $\lambda$ is strict, and $\phi(V_\lambda) = 0$ for non-strict partitions $\lambda$. The Pieri rule for the products $q_p \cdot Q_\lambda$ may therefore be obtained by specializing Morris’ rule (17) for the Hall-Littlewood symmetric functions when $t = -1$. The Pieri and Giambelli formulas for the Lagrangian Grassmannian $LG(n, 2n)$ were proved by Hiller and Boe [HB] and Pragacz [Pra], respectively.

4. Mirror identities and recursion formulas

4.1. Let $\lambda$ be any partition of length $\ell$. Our proof of the Pieri rule for $V_\lambda$ in §2.2 began with the equation

\[ v_p \cdot V_\lambda = v_p \cdot R v_\lambda = R v_{(\lambda, p)} \]

for an appropriate raising operator $R$, and relied on the identity

\begin{equation}
\sum_{\alpha \geq 0} (1 - t)^{\# \alpha} V_{\lambda + \alpha} = \sum_{\mu} \psi_{\mu/\lambda}(t) V_\mu
\end{equation}

where the first sum is over all compositions $\alpha$ of length at most $\ell + 1$, and the second over partitions $\mu \supset \lambda$ such that $\mu/\lambda$ is a horizontal strip. On the other hand, we may write $v_p \cdot R v_\lambda = R' v_{(p, \lambda)}$ for a raising operator $R'$ which agrees with $R$ up to a shift of its indices, and attempt a similar analysis. When $p$ is sufficiently large, we are led to the \textit{mirror identity} to (27), which is an analogous formula for the sum $\sum_{\alpha \geq 0} (1 - t)^{\# \alpha} V_{\lambda - \alpha}$.

We will require an auxiliary result which stems from [BKT3].

Lemma 5. Let $P_r$ be the set of partitions $\mu$ with $|\mu| = r$, and let $m$ be a positive integer. Then the $\mathbb{Z}[t]$-linear map

\[ \phi : \bigoplus_{r=0}^{m-1} \bigoplus_{\mu \in P_r} \mathbb{Z}[t] \to A_t \]

which, for given $r$ and $\mu \in P_r$, sends the corresponding basis element to $v_{m-r} V_\mu$, is injective.
Proof. The Pieri rule (17) implies that the image of $\phi$ is contained in the linear span of the elements $V_{(m-r,\mu)}$ for $0 < r < M$ and $\mu$ in $P_r$. Now the linear map $\phi$ is represented by a block triangular matrix with invertible diagonal matrices as the blocks along the diagonal, and hence is an isomorphism onto its image. □

Suppose $\mu$ is a partition with $\mu \subset \lambda$ such that $\lambda/\mu$ is a horizontal strip. Let $I$ denote the set of integers $c \geq 1$ such that $\lambda/\mu$ does (respectively does not) have a box in column $c$ (respectively column $c + 1$). Define

$$\varphi_{\lambda/\mu}(t) = \prod_{c \in I} (1 - t^{m_c(\lambda)})$$

and observe that for $p \geq \lambda_1$, the Pieri rule (17) for $v_p \cdot V_\lambda$ may be written in the form

$$(28) \quad v_p \cdot V_\lambda = \sum_{r \geq 0} \sum_{\mu \subset \lambda} \varphi_{\lambda/\mu}(t) V_{(p+r,\mu)}.$$ 

Theorem 1. For any partition $\lambda$, we have

$$(29) \quad \sum_{\alpha \geq 0} (1 - t)^{#\alpha} V_{\lambda - \alpha} = \sum_{\mu \subset \lambda} \varphi_{\lambda/\mu}(t) V_{\mu},$$

where the first sum is over all compositions $\alpha$, and the second over partitions $\mu \subset \lambda$ such that $\lambda/\mu$ is a horizontal strip.

Proof. Choose $p > |\lambda|$ and let $\ell = \ell(\lambda)$. Expanding the Giambelli formula with respect to the first row gives

$$(30) \quad v_p \cdot V_\lambda = \sum_{\alpha \geq 0} (1 - t)^{#\alpha} V_{(p+|\alpha|,\lambda-\alpha)}.$$ 

We compare (28) with (30), and claim that for every integer $r \geq 0$,

$$(31) \quad \sum_{|\alpha|=r} (1 - t)^{#\alpha} V_{(p+r,\lambda-\alpha)} = \sum_{\mu \subset \lambda} \varphi_{\lambda/\mu}(t) V_{(p+r,\mu)}.$$ 

The proof is by induction on $r$, with the case $r = 0$ being a tautology. For the induction step, suppose that we have for some $r > 0$ that

$$(32) \quad \sum_{s \geq r} \sum_{|\alpha|=s} (1 - t)^{#\alpha} V_{(p+s,\lambda-\alpha)} = \sum_{\mu \subset \lambda} \sum_{|\mu|=|\lambda|-s} \varphi_{\lambda/\mu}(t) V_{(p+s,\mu)}.$$ 

Expanding the Giambelli formula with respect to the first component, we obtain $v_{p+s} V_{\lambda-\alpha}$ as the leading term of $V_{(p+s,\lambda-\alpha)}$, while $v_{p+s} V_{\mu}$ is the leading term of $V_{(p+s,\mu)}$. Using these in (32) together with Lemma 5 proves that

$$(33) \quad \sum_{|\alpha|=r} (1 - t)^{#\alpha} V_{\lambda-\alpha} = \sum_{\mu \subset \lambda} \varphi_{\lambda/\mu}(t) V_{\mu}.$$ 

Proposition 1 now shows that (33) holds for every integer $r \geq 0$, the proof of Theorem 1 is complete. □
4.2. Let \( \lambda \) be any \( k \)-strict partition of length \( \ell \). In this section, we will obtain the mirror identity to the following version of (23):

\[
\sum_{\alpha \geq 0} W_{\lambda + \alpha}^{C(\lambda)} = \sum_{\lambda \rightarrow \mu} 2^{N(\lambda,\mu)} W_{\mu}^{C(\mu)}
\]

where the first sum is over all compositions \( \alpha \) of length at most \( \ell + 1 \), and the second over \( k \)-strict partitions \( \mu \) with \( \lambda \rightarrow \mu \).

**Proposition 2.** Let \( \Psi = \prod_{j=2}^{\ell+1} \frac{1 - R_{1j}}{1 + R_{1j}} \), and suppose that we have an equation

\[
\sum_{\nu} a_{\nu} w_{\nu} = \sum_{\nu} b_{\nu} w_{\nu}
\]

in \( B^{(k)} \), where the sums are over all \( \nu = (\nu_1, \ldots, \nu_\ell) \), while \( a_{\nu} \) and \( b_{\nu} \) are integers only finitely many of which are non-zero. Then we have

\[
\sum_{\nu} a_{\nu} \Psi w_{(p,\nu)} = \sum_{\nu} b_{\nu} \Psi w_{(p,\nu)}
\]

in the ring \( B^{(k)} \), for any integer \( p \).

**Proof.** It suffices to show that \( \sum_{\nu} c_{\nu} w_{\nu} = 0 \) implies that \( \sum_{\nu} c_{\nu} \Psi w_{(p,\nu)} = 0 \). We may assume by interchanging rows that the sum is over partitions \( \nu \), because

\[
\Psi w_{(p,\nu)} = \Psi w_{(p,\tau(\nu))}
\]

for every permutation \( \tau \) in the symmetric group \( S_\ell \), and \( w_{p,\nu} = \Psi w_{(p,\nu)} = 0 \) whenever \( \nu \) has a negative component. Recall that the \( w_{\nu} \) for \( k \)-strict partitions \( \nu \) form a \( \mathbb{Z} \)-basis for \( B^{(k)} \). Using the relations (18) and induction on the dominance order, we see that for any partition \( \nu \), either \( \nu \) is \( k \)-strict, or \( w_{\nu} \) is a \( \mathbb{Z} \)-linear combination of the \( w_{\mu} \) such that \( \mu \) is \( k \)-strict and \( \mu \succ \nu \).

It follows that we can identify the sum \( \sum_{\nu} c_{\nu} w_{\nu} \) with a \( \mathbb{Z} \)-linear combination of relations of the form \( \frac{1 - R_{h,h+1}^{(k)}}{1 + R_{h,h+1}^{(k)}} w_{\nu} \), where \( h \geq 1 \) and \( \nu \) is a partition such that \( \nu_h = \nu_{h+1} > k \). Therefore it will suffice to show that any such relation

\[
\frac{1 - R_{h,h+1}^{(k)}}{1 + R_{h,h+1}^{(k)}} w_{\nu} = 0
\]

implies that \( \Psi \frac{1 - R_{h,h+1}^{(k)}}{1 + R_{h,h+1}^{(k)}} w_{(p,\nu)} = 0 \). For this, it is enough to check that

\[
\frac{1 - R_{1,h}^{(k)}}{1 + R_{1,h}^{(k)}} \cdot \frac{1 - R_{1,h+1}^{(k)}}{1 + R_{1,h+1}^{(k)}} \cdot \frac{1 - R_{h,h+1}^{(k)}}{1 + R_{h,h+1}^{(k)}} w_{(p,\nu)} = 0.
\]

But we have

\[
\frac{1 - R_{1,h}^{(k)}}{1 + R_{1,h}^{(k)}} \cdot \frac{1 - R_{1,h+1}^{(k)}}{1 + R_{1,h+1}^{(k)}} = 1 - \frac{R_{1,h}^{(k)}}{1 + R_{1,h}^{(k)}} - \frac{R_{1,h+1}^{(k)}}{1 + R_{1,h+1}^{(k)}} + \frac{R_{h,h+1}^{(k)}}{1 + R_{h,h+1}^{(k)}}
\]

and since \( \nu_h = \nu_{h+1} \), the result is clear. \( \square \)

The next result is an easy consequence of the Pieri rule (22).

**Lemma 6 ([BKT3]).** Let \( \lambda \) and \( \nu \) be \( k \)-strict partitions such that \( \nu_1 > \max(\lambda_1, \ell(\lambda) + 2k) \) and \( p \geq 0 \). Then the coefficient of \( W_{\nu} \) in the Pieri product \( w_{p,\nu} \cdot W_{\lambda} \) is equal to the coefficient of \( W_{(\nu_1+1,\nu_2,\nu_3,\ldots)} \) in the product \( w_{p+1} \cdot W_{\lambda} \).

We apply Lemma 6 to make the following important definition.
Definition 1. Let \( \lambda \) and \( \mu \) be \( k \)-strict partitions with \( \mu \subset \lambda \), and choose any \( p \geq \max(\lambda_1 + 1, \ell(\lambda) + 2k) \). If \( |\lambda| = |\mu| + r \) and \( \lambda \rightarrow (p + r, \mu) \), then we write \( \mu \rightarrow \lambda \) and say that \( \lambda/\mu \) is a \( k \)-horizontal strip. We define \( n(\lambda/\mu) := N(\lambda, (p + r, \mu)) \); in other words, the numbers \( n(\lambda/\mu) \) are the exponents that appear in the Pieri product
\[
(34) \quad w_p \cdot W_\lambda = \sum_{r,\mu} 2^{n(\lambda/\mu)} W_{(p+r,\mu)}
\]
with the sum over integers \( r \geq 0 \) and \( k \)-strict partitions \( \mu \subset \lambda \) with \( |\mu| = |\lambda| - r \).

Note that a \( k \)-horizontal strip \( \lambda/\mu \) is a pair of partitions \( \lambda \) and \( \mu \) with \( \mu \rightarrow \lambda \). As such it depends on \( \lambda \) and \( \mu \) and not only on the difference \( \lambda \triangle \mu \). A similar remark applies to the integer \( n(\lambda/\mu) \) and the polynomials \( \varphi_{\lambda/\mu}(t), \psi_{\lambda/\mu}(t) \) of \( \S 4.1 \). Observe also that \( n(\lambda/\lambda) = 0 \) and \( n(\lambda/\mu) \geq 1 \) whenever \( \lambda \neq \mu \). We will study the relation \( \mu \rightarrow \lambda \) and the integer \( n(\lambda/\mu) \) in more detail in \( \S 5.3 \).

Theorem 2. For \( \lambda \) any \( k \)-strict partition we have
\[
(35) \quad \sum_{\alpha \geq 0} 2^{|\alpha|} W^{C(\lambda)}_{\lambda - \alpha} = \sum_{\mu \rightarrow \lambda} 2^{n(\lambda/\mu)} W_\mu,
\]
where the first sum is over all compositions \( \alpha \).

Proof. The argument is essentially the same as that in the proof of Theorem 1. We choose \( p > |\lambda| + 2k \) and prove by induction that for each \( r \geq 0 \),
\[
\sum_{|\alpha|=r} 2^{|\alpha|} W^{\tilde{C}}_{(p+r,\lambda - \alpha)} = \sum_{|\mu|=|\lambda| - r} 2^{n(\lambda/\mu)} W_{(p+r,\mu)},
\]
where \( \tilde{C} = C((p, \lambda)) \). Clearly we have an analogue of Lemma 5 which holds for the algebra \( B^{(k)} \), and we use Proposition 2 as a substitute for Proposition 1. The point is that for such integers \( p \) and \( r \), the raising operator expressions \( R^{\tilde{C}} \) and \( R^{(p+r,\mu)} \)
both contain the product \( \Psi = \prod_{j=2}^{\ell+1} \frac{1 - R_{1j}}{1 + R_{1j}} \), where \( \ell = \ell(\lambda) \).

4.3. We now give some consequences of the previous mirror identities for the Schur \( S \)- and \( Q \)-functions. Given any integer sequence \( \nu \), let \( s_\nu(x) \) and \( Q_\nu(x) \) denote the Schur functions defined in \( \S 2.3 \) and \( \S 3.3 \), respectively. When \( t = 0 \), Theorem 1 specializes to the following well known result.

Corollary 2. For any partition \( \lambda \), we have
\[
\sum_{\alpha \geq 0} s_{\lambda - \alpha}(x) = \sum_{\mu} s_\mu(x),
\]
where the first sum is over all compositions \( \alpha \) and the second over all partitions \( \mu \subset \lambda \) such that \( \lambda/\mu \) is a horizontal strip.

The rim of a partition \( \lambda \) is the set of boxes \([r, c]\) of its Young diagram such that box \([r + 1, c + 1]\) lies outside the diagram of \( \lambda \). If we choose \( k > \ell(\lambda) \) in Theorem 2, then we have \( \tilde{C}(\lambda) = \emptyset \) and can thus deduce the following result.

Corollary 3. For any partition \( \lambda \), we have
\[
\sum_{\alpha \geq 0} 2^{|\alpha|} s_{\lambda - \alpha}(x) = \sum_{\mu} 2^{n(\lambda/\mu)} s_\mu(x),
\]
where the first sum is over all compositions \( \alpha \) and the second over all partitions \( \mu \subset \lambda \) such that \( \lambda/\mu \) is contained in the rim of \( \lambda \), and \( n(\lambda/\mu) \) equals the number of edge-connected components of \( \lambda/\mu \).

The shifted diagram of a strict partition \( \lambda \), denoted \( S(\lambda) \), is obtained from the usual Young diagram by shifting the \( i \)-th row \((i-1)\) squares to the right, for every \( i > 1 \). Moreover, when \( \mu \) is a strict partition with \( \mu \subset \lambda \), we set \( S(\lambda/\mu) = S(\lambda) \setminus S(\mu) \). We introduce this notation to emphasize the similarity between Corollary 3 and the next result, which follows by setting \( k = 0 \) in Theorem 2.

**Corollary 4.** For any strict partition \( \lambda \), we have
\[
\sum_{\alpha \geq 0} 2^{\# \alpha} Q_{\lambda-\alpha}(x) = \sum_{\mu} 2^{n(\lambda/\mu)} Q_\mu(x),
\]
where the first sum is over all compositions \( \alpha \) and the second over all strict partitions \( \mu \subset \lambda \) such that \( S(\lambda/\mu) \) is contained in the rim of \( S(\lambda) \), and \( n(\lambda/\mu) \) equals the number of edge-connected components of \( S(\lambda/\mu) \).

### 4.4
We next show how the raising operator formalism we have developed may be used to obtain a recursion formula for the basis elements \( W_\lambda \), expressed in terms of the length of \( \lambda \). This question came up naturally during our work on Giambelli formulas for the quantum cohomology ring of isotropic Grassmannians [BKT3, §1.3].

Throughout this subsection \( \lambda \) is a partition of length \( \ell \) and \( p \geq \lambda_1 \) is an integer. For completeness, we begin with the kind of recursion we have in mind for the elements \( U(p,\lambda) \) of §1. We claim that for any partition \( \lambda \) and \( p \geq \lambda_1 \), we have
\[
U(p,\lambda) = \sum_{r,\mu} (-1)^r u_{p+r} U_\mu
\]
where the sum is over integers \( r \geq 0 \) and partitions \( \mu \) obtained from \( \lambda \) by removing a vertical strip with \( r \) boxes. Indeed, Applying the definition (2) gives
\[
U(p,\lambda) = \prod_{j>i>1} (1-R_{ij}) \prod_{j>1} (1-R_{1j}) u_{(p,\lambda)} = \sum_{r,\nu} (-1)^r u_{p+r} U_\nu
\]
where the sum is over integers \( r \geq 0 \) and compositions \( \nu \) obtained from \( \lambda \) by removing \( r \) boxes, no two in the same row. If \( \nu \) is not a partition, then we must have \( \nu_{j+1} = \nu_j + 1 \) for some \( j \); hence \( U_\nu = 0 \) by Lemma 1. The result follows.

The analogue of equation (36) for the \( W(p,\lambda) \) when \( p \) and \( \lambda \) are arbitrary appears complicated. The next theorem gives a top row recursion for sufficiently large \( p \).

**Theorem 3.** For any \( k \)-strict partition \( \lambda \) and \( p \geq \max(\lambda_1 + 1, \ell(\lambda) + 2k) \), we have
\[
W(p,\lambda) = \sum_{r,\mu} (-1)^r 2^{n(\lambda/\mu)} u_{p+r} W_\mu,
\]
where the sum is over \( r \geq 0 \) and \( \mu \sim \lambda \) with \( |\mu| = |\lambda| - r \).

**Proof.** The Giambelli formula for \( W(p,\lambda) \) implies that
\[
W(p,\lambda) = R_{\lambda}^{\ell+1} \prod_{j=2}^{\ell} \frac{1-R_{1j}}{1+R_{1j}} w_{(p,\lambda)} = \sum_\alpha (-1)^{|\alpha|} 2^{\# \alpha} u_{p+|\alpha|} W_{\lambda-\alpha}^C(\lambda)
\]
where \( \mathcal{C} \) denotes the image of \( \mathcal{C}(\lambda) \) under the map which sends \( (i, j) \) to \( (i+1, j+1) \).

We obtain

\[
W_{(p, \lambda)} = \sum_{r \geq 0} (-1)^r w_{p+r} \sum_{|\alpha|=r} 2^{|x|_{\alpha}} W_{\lambda\alpha}^C(\lambda)
\]

and then apply the mirror identity (35) to finish the proof.

The reader should compare the stable Pieri rule (34) with the recursion formula (37). This is illustrated in the next example.

**Example 6.** For \( k = 2 \) and \( \lambda = (7, 4, 2, 1) \), we have

\[
w_7 \cdot W_{4,2,1} = W_{7,4,2,1} + 2 W_{8,3,2,1} + 2 W_{8,4,2} + 2 W_{9,2,2,1} + 2 W_{9,3,1,1} + 4 W_{9,3,2} + 2 W_{10,2,1,1} + 4 W_{10,2,2} + 4 W_{10,3,1} + 4 W_{11,2,1} + 2 W_{11,3} + 2 W_{12,2},
\]

and hence

\[
W_{7,4,2,1} = w_7 \cdot W_{4,2,1} - w_8 (2 W_{3,2,1} + 2 W_{4,2}) + w_9 (2 W_{2,2,1} + 2 W_{3,1,1} + 4 W_{3,2}) - w_{10} (2 W_{2,1,1} + 4 W_{2,2} + 4 W_{3,1}) + w_{11} (4 W_{2,1} + 2 w_3) - 2 w_{12} w_2.
\]

Setting \( k = 0 \) in Theorem 3 produces the following recursion formula for Schur \( Q \)-functions.

**Corollary 5.** For any strict partition \( \lambda \) and \( p > \lambda_1 \), we have

\[
Q_{(p, \lambda)}(x) = \sum_{r, \mu} (-1)^r 2^{n(\lambda/\mu)} q_{p+r}(x) Q_{\mu}(x)
\]

where the sum is over \( r \geq 0 \) and strict partitions \( \mu \subset \lambda \) such that \( \lambda/\mu \) is a horizontal \( r \)-strip, and \( n(\lambda/\mu) \) equals the number of connected components of \( \lambda/\mu \).

Observe that (38) is a generalization of Schur’s identity

\[
Q_{a,b}(x) = q_a(x) q_b(x) - 2 q_{a+1}(x) q_{b-1}(x) + 2 q_{a+2}(x) q_{b-2}(x) - \cdots
\]

for any integers \( a, b \) with \( a > b \geq 0 \).

It would be interesting to prove a top row recursion formula for the \( W_\lambda \) polynomials analogous to (37) in the general case, as well as for the \( V_\lambda \) polynomials (in the Hall-Littlewood theory). Note that both of these recursions would have to interpolate between formula (36), which arises when \( k \) is sufficiently large for the \( W_\lambda \) and when \( t = 0 \) for the \( V_\lambda \), and formula (38), which arises when \( k = 0 \) or \( t = -1 \), respectively.

## 5. Reduction Formulas and Tableaux

### 5.1. The mirror identity (29) may be applied in the theory of Hall-Littlewood functions \( Q_\lambda(x; t) \) of §2.3 to obtain a reduction formula; what is being reduced is the number of \( x \) variables used in the argument of \( Q_\lambda(x; t) \). Let \( \tilde{x} = (x_2, x_3, \ldots) \) and observe that \( q_p(x; t) = \sum_{i=0}^p q_i(x_1; t) q_{p-i}(\tilde{x}; t) \).

Therefore, for any integer sequence \( \lambda \), we obtain

\[
q_\lambda(x; t) = \sum_{\alpha \geq 0} q_\alpha(x_1; t) q_{\lambda-\alpha}(\tilde{x}; t) = \sum_{\alpha \geq 0} x_1^{[\alpha]} (1 - t)^{|\alpha|} q_{\lambda-\alpha}(\tilde{x}; t)
\]

summed over all compositions \( \alpha \). If \( R \) denotes any raising operator, we have

\[
R q_\lambda(x; t) = q_{\lambda R}(x; t) = \sum_{\alpha \geq 0} q_\alpha(x_1; t) q_{\lambda R-\alpha}(\tilde{x}; t) = \sum_{\alpha \geq 0} q_\alpha(x_1; t) R q_{\lambda-\alpha}(\tilde{x}; t).
\]
Applying the Giambelli formula to (39), we thus deduce that for any partition \( \lambda \), we have

\[
Q_\lambda(x; t) = \sum_{\alpha \geq 0} x_1^{|\alpha|} (1 - t)^{#_\alpha} Q_{\lambda - \alpha}(\tilde{x}; t) = \sum_{p=0}^{\infty} x_1^p \sum_{|\alpha| = p} (1 - t)^{#_\alpha} Q_{\lambda - \alpha}(\tilde{x}; t)
\]

and hence, using (29), the reduction formula

\[
Q_\lambda(x; t) = \sum_{p=0}^{\infty} x_1^p \sum_{\mu \subseteq \lambda - p} \varphi_{\lambda/\mu}(t) Q_{\mu}(\tilde{x}; t)
\]

with the second sum over partitions \( \mu \subset \lambda \) such that \( \lambda/\mu \) is a horizontal \( p \)-strip. Repeated application of the reduction equation (41) results in the tableau formula of [M, III.(5.11)] for the Hall-Littlewood functions.

There is an alternative approach to the proof of (41) which applies standard symmetric function theory, as in e.g. [M, III.5]. If \( x' = (x_1', x_2', \ldots) \) is a second set of commuting variables, then the equation

\[
Q_\lambda(x', t) = \sum_{\mu} Q_{\lambda/\mu}(x; t) Q_{\mu}(\tilde{x}; t)
\]

summed over partitions \( \mu \subset \lambda \) may be used to define the skew Hall-Littlewood functions \( Q_{\lambda/\mu}(x; t) \). In particular, this gives

\[
Q_\lambda(x_1, x; t) = \sum_{\mu} Q_{\lambda/\mu}(x_1; t) Q_{\mu}(\tilde{x}; t).
\]

According to [M, III.(5.14)], we have

\[
Q_{\lambda/\mu}(x_1; t) = \varphi_{\lambda/\mu}(t) x_1^{|\lambda - \mu|}
\]

and hence (41) is established. By comparing with (40), we can apply this reasoning to prove the mirror identity (29) for the Hall-Littlewood functions. Note however that the proof of (42) uses the inner product of [M, III.4], and the point here is that this is not needed in order to establish Theorem 1 (which of course does not involve the variables \( x \)). The raising operator approach will be exploited further in the next subsections when we study theta polynomials.

5.2. Let \( y = (y_1, \ldots, y_k) \) and consider the theta polynomials \( \vartheta_r(x; y) \) and \( \Theta_\lambda(x; y) \) defined in §3.3, so that \( \Theta_\lambda = R^\lambda \vartheta_\lambda \) for any \( k \)-strict partition \( \lambda \). We compute that

\[
\sum_{r=0}^{\infty} \vartheta_r(x; y)t^r = \frac{1 + x_1t}{1 - x_1t} \prod_{i=2}^{k} \frac{1 + x_it}{1 - x_it} \prod_{j=1}^{k} (1 + y_j t) = \sum_{r=0}^{\infty} 2^{|\alpha|} x_1^i \sum_{r=0}^{\infty} \vartheta_r(\tilde{x}; y)
\]

and therefore, for any \( k \)-strict partition \( \lambda \),

\[
\vartheta_\lambda(x; y) = \sum_{\alpha \geq 0} x_1^{|\alpha|} 2^{|\alpha|} \vartheta_{\lambda - \alpha}(\tilde{x}; y)
\]

summed over all compositions \( \alpha \). Applying the raising operator \( R^\lambda \) to both sides of (43) produces

\[
\Theta_\lambda(x; y) = \sum_{\alpha \geq 0} x_1^{|\alpha|} 2^{|\alpha|} \Theta_{\lambda - \alpha}^{(\lambda)}(\tilde{x}; y) = \sum_{p=0}^{\infty} x_1^p \sum_{|\alpha| = p} 2^{|\alpha|} \Theta_{\lambda - \alpha}^{(\lambda)}(\tilde{x}; y),
\]
where $\Theta^{c(\lambda)}_{\alpha} = R^\lambda \vartheta_{\lambda - \alpha}$ by definition. We now use the mirror identity (35) to deduce the next result.

**Theorem 4.** For any $k$-strict partition $\lambda$, we have the reduction formula

$$\Theta_{\lambda}(x; y) = \sum_{p=0}^{\infty} x_p \sum_{\mu \rightarrow \lambda} 2^{n(\lambda/\mu)} \Theta_{\mu}(\bar{x}; y).$$

5.3. In this subsection we will apply the reduction formula (44) to obtain a tableau description of the theta polynomials $\Theta_{\lambda}$, where the tableaux in question are fillings of the Young diagram of $\lambda$. We say that boxes $[r, c]$ and $[r', c']$ are $k'$-related if $|c - k - \frac{1}{2}| + r = |c' - k - \frac{1}{2}| + r'$ (we think of $k'$ as being equal to $k - \frac{1}{2}$). For example, the two grey boxes in the diagram of Figure 3 are $k'$-related. We call box $[r, c]$ a left box if $c \leq k$ and a right box if $c > k$.

If $\mu \subset \lambda$ are two $k$-strict partitions such that $\lambda/\mu$ is a $k'$-horizontal strip, we define $\lambda_0 = \mu_0 = \infty$ and agree that the diagrams of $\lambda$ and $\mu$ include all boxes $[0, c]$ in row zero. We let $R$ (respectively $A$) denote the set of right boxes of $\lambda$ (including boxes in row zero) which are bottom boxes of $\lambda$ in their column and are (respectively are not) $k'$-related to a left box of $\lambda/\mu$.

**Lemma 7.** A pair $\mu \subset \lambda$ of $k$-strict partitions forms a $k$-horizontal strip $\lambda/\mu$ if and only if (i) $\lambda/\mu$ is contained in the rim of $\lambda$, and the right boxes of $\lambda/\mu$ form a horizontal strip; (ii) no two boxes in $R$ are $k'$-related; and (iii) if two boxes of $\lambda/\mu$ lie in the same column, then they are $k'$-related to exactly two boxes of $R$, which both lie in the same row. The integer $n(\lambda/\mu)$ is equal to the number of connected components of $k$ which do not have a box in column $k + 1$.

**Proof.** We have $\mu \rightarrow \lambda$ if and only if $\lambda \rightarrow (p + r, \mu)$ for any $p > |\lambda| + 2k$, where $r = |\lambda - \mu|$. Observe that a box of $(p + r, \mu)$ corresponds to a box of $\mu$ which is a bottom box of $\lambda$ in its column. The fact that $\mu \rightarrow \lambda$ is characterized by conditions (i)–(iii) and that $n(\lambda/\mu) = N(\lambda, (p + r, \mu))$ is computed as claimed is now an easy translation of the definitions in §3.2. \hfill $\square$

Let $\lambda$ and $\mu$ be any two $k$-strict partitions with $\mu \subset \lambda$.

**Definition 2.** a) A $k$-tableau $T$ of shape $\lambda/\mu$ is a sequence of $k$-strict partitions

$$\mu = \lambda^0 \subset \lambda^1 \subset \cdots \subset \lambda^r = \lambda$$

such that $\lambda^i/\lambda^{i-1}$ is a $k$-horizontal strip for $1 \leq i \leq r$. We represent $T$ by a filling of the boxes in $\lambda/\mu$ with positive integers which is weakly increasing along each row and down each column, such that for each $i$, the boxes in $T$ with entry $i$ form...
the skew diagram $\lambda^i/\lambda^{i-1}$. A **standard $k$-tableau** on $\lambda/\mu$ is a $k$-tableau $T$ of shape $\lambda/\mu$ such that the entries $1, 2, \ldots, |\lambda - \mu|$ each appear once in $T$. For any $k$-tableau $T$ we define
\[
n(T) = \sum_i n(\lambda^i/\lambda^{i-1}) \quad \text{and} \quad x^T = \prod_i x_i^{m_i},\]
where $m_i$ denotes the number of times that $i$ appears in $T$.

b) Let $P$ denote the ordered alphabet $\{1' < 2' < \cdots < k' < 1 < 2 < \cdots\}$. The symbols $1', \ldots, k'$ are said to be **marked**, while the rest are **unmarked**. A $k$-**bitableau** $U$ of shape $\lambda$ is a filling of the boxes in $\lambda$ with elements of $P$ which is weakly increasing along each row and down each column, such that (i) the marked entries are strictly increasing along each row, and (ii) the unmarked entries form a $k$-tableau $T$. We define
\[
n(U) = n(T) \quad \text{and} \quad (xy)^U = x^T \prod_{j=1}^k y_j^{n_j},\]
where $n_j$ denotes the number of times that $j'$ appears in $U$.

**Theorem 5.** For any $k$-strict partition $\lambda$, we have
\[
\Theta_{\lambda}(x; y) = \sum_U 2^{n(U)} (xy)^U
\]
where the sum is over all $k$-bitableaux $U$ of shape $\lambda$.

**Proof.** Let $m$ be a positive integer, $x^{(m)} = (x_1, \ldots, x_m)$, and let $\Theta_{\lambda}(x^{(m)}; y)$ be the result of substituting $x_i = 0$ for $i > m$ in $\Theta_{\lambda}(x; y)$. It follows from equation (44) that
\[
\Theta_{\lambda}(x^{(m)}; y) = \sum_{p=0}^{\infty} x_1^p \sum_{\mu \subset \lambda} 2^{n(\lambda/\mu)} \Theta_{\mu}(x^{(m-1)}; y).
\]
Iterating equation (46) $m$ times produces
\[
\Theta_{\lambda}(x^{(m)}; y) = \sum_{\mu, T} 2^{n(T)} x^T \Theta_{\mu}(0; y)
\]
where the sum is over all $k$-strict partitions $\mu \subset \lambda$ and $k$-tableau $T$ of shape $\lambda/\mu$ with no entries greater than $m$, and $\Theta_{\mu}(0; y)$ is obtained from $\Theta_{\lambda}(x; y)$ by substituting $x_i = 0$ for all $i$. The raising operator definition of $\Theta_{\mu}$ gives
\[
\Theta_{\mu}(0; y) = R^\mu e_{\mu}(y)
\]
where $e_{\mu} = \prod_i e_{\mu_i}(y)$ and $e_r(y)$ denotes the $r$-th elementary symmetric polynomial in $y$. Since $e_r(y) = 0$ for $r > k$, we deduce from (47) that $\Theta_{\mu}(0; y) = 0$ unless $\mu$ is contained in the first $k$ columns. But in this case we have $C(\mu) = \emptyset$ and
\[
\Theta_{\mu}(0; y) = \prod_{i<j} (1 - R_{ij}) e_{\mu_i}(y) = s_{\mu'}(y)
\]
where $\mu'$ is the partition conjugate to $\mu$. The combinatorial definition of Schur $S$-functions [M, I.(5.12)] states that
\[
s_{\mu'}(y) = \sum_S y^S
summed over all semistandard Young tableaux $S$ of shape $\mu'$ with entries from 1 to $k$. In the spirit of this article, the identity (48) may be derived using raising operators, by iterating the specialization of equation (41) at $t = 0$. We conclude that

$$\Theta_{\lambda}(x^{(m)}; y) = \sum_{U} 2^{n(U)} (xy)^{U}$$

summed over all $k$-bitableaux $U$ of shape $\lambda$ with no entries greater than $m$. The result follows by letting $m \to \infty$. \hfill \square

**Example 7.** Let $k = 1$, $\lambda = (3, 1)$, and consider the alphabet $P_{1,2} = \{1' < 1 < 2\}$. There are twelve $k$-bitableaux $T$ of shape $\lambda$ with entries in $P_{1,2}$. The bitableau $T = 1'12$ satisfies $n(T) = 3$, the seven bitableaux

\[
\begin{array}{ccccccc}
112 & 112 & 122 & 122 & 1'12 & 1'22 & 1'12 \\
1 & 2 & 1 & 2 & 2 & 1 & 1
\end{array}
\]

satisfy $n(T) = 2$, while the four bitableaux

\[
\begin{array}{ccccccc}
1'11 & 1'22 & 1'11 & 1'22 \\
1 & 2 & 1' & 1'
\end{array}
\]

satisfy $n(T) = 1$. We deduce from Theorem 5 that

$$\Theta_{3,1}(x_1, x_2; y_1) = (4x_1^3x_2 + 8x_1^2x_2^2 + 4x_1x_2^3) + (2x_1^3 + 8x_1^2x_2 + 8x_1x_2^2 + 2x_2^3)y_1 + (2x_1^2 + 4x_1x_2 + 2x_2^2)y_1^2 = Q_{3,1}(x_1, x_2) + (Q_{3}(x_1, x_2) + Q_{2,1}(x_1, x_2)) y_1 + Q_{2}(x_1, x_2)y_1^2.$$

**5.4.** Notice that (45) may be rewritten as

$$\Theta_{\lambda}(x; y) = \sum_{\mu, T} 2^{n(T)} x^T s_{\mu'}(y)$$

with the sum over all partitions $\mu \subset \lambda$ and $k$-tableau $T$ of shape $\lambda/\mu$. This motivates the following definition.

**Definition 3.** For $\lambda$ and $\mu$ any two $k$-strict partitions with $\mu \subset \lambda$, let

$$F_{\lambda/\mu}^{(k)}(x) = \sum_{T} 2^{n(T)} x^T$$

where the sum is over all $k$-tableaux $T$ of shape $\lambda/\mu$.

**Corollary 6.** Let $x = (x_1, x_2, \ldots)$ and $x' = (x'_1, x'_2, \ldots)$ be two sets of variables, and let $\lambda$ be any $k$-strict partition. Then we have

(49) \hspace{2cm} \Theta_{\lambda}(x, x'; y) = \sum_{\mu \subset \lambda} F_{\lambda/\mu}^{(k)}(x) \Theta_{\mu}(x'; y),

(50) \hspace{2cm} \Theta_{\lambda}(x; y) = \sum_{\mu \subset \lambda} F_{\lambda/\mu}^{(k)}(x) s_{\mu'}(y),

and

(51) \hspace{2cm} F_{\lambda}^{(k)}(x, x') = \sum_{\mu \subset \lambda} F_{\lambda/\mu}^{(k)}(x) F_{\mu}^{(k)}(x'),

where the sums are over all $k$-strict partitions $\mu \subset \lambda$. 
Proof. Let \( m \) be a positive integer, \( x^{(m)} = (x_1, \ldots, x_m) \), and let \( F_{\lambda/\mu}^{(k)}(x^{(m)}) \) (respectively \( \Theta_{\lambda}(x^{(m)}; y) \)) be the result of substituting \( x_i = 0 \) for \( i > m \) in \( F_{\lambda/\mu}^{(k)}(x) \) (respectively \( \Theta_{\lambda}(x; y) \)). Applying equation (46) as in the proof of Theorem 5 gives
\[
\Theta_{\lambda}(x^{(m)}, x'; y) = \sum_{\mu \subseteq \lambda} F_{\lambda/\mu}^{(k)}(x^{(m)}) \Theta_{\mu}(x'; y).
\]
Now let \( m \to \infty \) to obtain (49). Equations (50) and (51) are deduced from (49) by substituting \( x' = 0 \) and \( y = 0 \), respectively.

The polynomials \( \Theta_{\mu}(x'; y) \) for \( \mu \) a \( k \)-strict partition form a free \( \mathbb{Z} \)-basis for the ring \( \Gamma^{(k)}(x'; y) \) of theta polynomials in \( x' \) and \( y \). The identity (49) states that \( F_{\lambda/\mu}^{(k)}(x) \) is the coefficient of \( \Theta_{\mu}(x'; y) \) when \( \Theta_{\lambda}(x, x'; y) \) is expanded in this basis.

We deduce that \( F_{\lambda/\mu}^{(k)}(x) \) is a symmetric function in the variables \( x \). The identity (51) may be further generalized as follows.

**Corollary 7.** For any two \( k \)-strict partitions \( \lambda \) and \( \mu \) with \( \mu \subset \lambda \), we have
\[
F_{\lambda/\mu}^{(k)}(x, x') = \sum_{\nu} F_{\lambda/\nu}^{(k)}(x) F_{\nu/\mu}^{(k)}(x'),
\]
where the sum is over all \( k \)-strict partitions \( \nu \) with \( \mu \subset \nu \subset \lambda \).

**Proof.** Let \( z = (z_1, z_2, \ldots) \) be a third set of variables. We have
\[
\sum_{\mu \subseteq \lambda} F_{\lambda/\mu}^{(k)}(x, x') \Theta_{\mu}(z; y) = \Theta_{\lambda}(x, x', z; y) = \sum_{\nu} F_{\lambda/\nu}^{(k)}(x) \Theta_{\nu}(x', z; y)
\]
\[
= \sum_{\mu, \nu} F_{\lambda/\nu}^{(k)}(x) F_{\nu/\mu}^{(k)}(x') \Theta_{\mu}(z; y).
\]
We now equate the coefficients of \( \Theta_{\mu}(z; y) \) at either end of the above equalities.

In the next section, we will show that the \( k \)-strict partitions \( \nu \) which contribute positively to the sum in equation (52) correspond to the reduced factorizations of a certain skew element in the hyperoctahedral group.

**Example 8.**

a) Suppose that \( k = 0 \) or, more generally, that \( \mu_i \geq \min(k, \lambda_i) \) for all \( i \). Then Definition 3 becomes the tableau based definition of skew Schur \( Q \)-functions [M, III.(8.16)], hence \( F_{\lambda/\mu}^{(k)}(x) = Q_{\lambda/\mu}(x) \).

b) Suppose that \( \mathcal{C}(\lambda) = \emptyset \), so in particular \( \lambda_i > k \) implies that \( i = 1 \). One then checks that \( n(\lambda/\mu) \) is equal to the number of edge-connected components of \( \lambda/\mu \).

For any partition \( \mu \subset \lambda \), Worley [W, §2.7] has shown that
\[
\sum_{T} 2^{n(T)} x^{T} = S_{\lambda/\mu}(x),
\]
where the symmetric function \( S_{\lambda/\mu}(x) \) satisfies
\[
S_{\lambda/\mu}(x) = \det(q_{\lambda_i-\mu_j+j-i}(x))_{i,j}.
\]
We therefore have \( F_{\lambda/\mu}^{(k)}(x) = S_{\lambda/\mu}(x) \) and
\[
\Theta_{\lambda}(x; y) = \sum_{\mu \subseteq \lambda} S_{\lambda/\mu}(x) s_{\mu'}(y),
\]
in agreement with [BKT2, §5.5].
c) It is clear from Definition 3 that in general, the skew function \( F_{\lambda/\mu}^{(k)}(x) \) depends on both \( \lambda \) and \( \mu \), and not only on the difference \( \lambda \setminus \mu \). For instance, we have \( F_{(3,2)/(3)}^{(1)}(x) = 0 \), while \( F_{(r,2)/(r)}^{(1)}(x) = Q_2(x) \) for any \( r > 3 \). On the other hand, \( F_{(5,4,1,1)/(4,3,3)}^{(1)}(x) = F_{(\lambda,5,4,1,1)/(4,4,3)}^{(1)}(x) = 0 \) for any strict partition \( \lambda \) with \( \lambda_1 > 5 \). Criteria for the vanishing of \( F_{\lambda/\mu}^{(k)}(x) \) are given in Proposition 6 and Corollary 10.

d) Suppose that there is only one variable \( x \). Then we have

\[
F_{\lambda/\mu}^{(k)}(x) = \begin{cases} 
2^{n(\lambda/\mu)} x^{\lambda/\mu} & \text{if } \lambda/\mu \text{ is a } k\text{-horizontal strip}, \\
0 & \text{otherwise}.
\end{cases}
\]

The reader should compare this to (42).

5.5. Observe that we have

\[
\vartheta_\mu(x, x'; y) = \sum_{i=0}^{\mu} q_i(x) \vartheta_{\mu-i}(x'; y)
\]

and therefore, for any \( k\)-strict partition \( \lambda \),

\[
\vartheta_\lambda(x, x'; y) = \sum_{\alpha \geq 0} q_\alpha(x) \vartheta_{\lambda-\alpha}(x'; y)
\]

summed over all compositions \( \alpha \geq 0 \). It follows that

\[
(53) \quad \Theta_\lambda(x, x'; y) = \sum_{\alpha \geq 0} q_\alpha(x) \Theta_{\lambda-\alpha}^{C(\lambda)}(x'; y).
\]

For each fixed composition \( \alpha \), the product \( q_\alpha(x) = \prod_i q_{\alpha_i}(x) \) is a nonnegative linear combination of Schur \( Q \)-functions. In addition, \( \Theta_{\lambda-\alpha}^{C(\lambda)}(x') \) is a \( \mathbb{Z} \)-linear combination of the \( \Theta_{\mu}(x'; y) \) for \( k\)-strict partitions \( \mu \). By comparing (53) with (49), we deduce that for every two \( k\)-strict partitions \( \lambda, \mu \) with \( \mu \subset \lambda \), the function \( F_{\lambda/\mu}^{(k)}(x) \) is a linear combination of Schur \( Q \)-functions with integer coefficients. In the next section, we will prove that these coefficients are nonnegative integers.

6. STANLEY SYMMETRIC FUNCTIONS AND SKEW ELEMENTS

6.1. Let \( B_n \) be the hyperoctahedral group of signed permutations on the set \( \{1, \ldots, n\} \), and \( B_\infty = \cup_n B_n \). We will adopt the notation where a bar is written over an entry with a negative sign. The group \( B_\infty \) is generated by the simple transpositions \( s_i = (i, i+1) \) for \( i > 0 \), and the sign change \( s_0(1) = 1 \). Every element \( w \in B_\infty \) can be expressed as a product of simple reflections \( s_i \); any such expression of minimal length is called a reduced word for \( w \). The length of \( w \), denoted \( \ell(w) \), is the length of any reduced word for \( w \). A factorization \( w = uv \) in \( B_\infty \) is reduced if \( \ell(w) = \ell(u) + \ell(v) \).

Following [FS] and [FK1, FK2], we will use the nilCoxeter algebra \( B_n \) of the hyperoctahedral group \( B_n \) to define type C Stanley symmetric functions and Schubert polynomials. \( B_n \) is the free associative algebra with unity generated by the elements \( u_0, u_1, \ldots, u_{n-1} \) modulo the relations

\[
\begin{align*}
u_i^2 &= 0, & i \geq 0; \\
u_i u_j &= u_j u_i, & |i - j| \geq 2; \\
u_i u_{i+1} u_i &= u_{i+1} u_i u_{i+1}, & i > 0; \\
u_0 u_1 u_0 u_1 &= u_1 u_0 u_1 u_0.
\end{align*}
\]
For any $w \in B_n$, choose a reduced word $s_{a_1} \cdots s_{a_t}$ for $w$ and define $u_w = u_{a_1} \cdots u_{a_t}$. Since the last three relations listed are the Coxeter relations for $B_n$, it is clear that $u_w$ is well defined, and that the $u_w$ for $w \in B_n$ form a free $\mathbb{Z}$-basis of $B_n$.

Let $\omega$ be an indeterminate and define
\[
A_i(\omega) = (1 + \omega u_{n-1})(1 + \omega u_{n-2}) \cdots (1 + \omega u_i); \quad C(\omega) = (1 + \omega u_{n-1}) \cdots (1 + \omega u_1) (1 + 2 \omega u_0) (1 + \omega u_1) \cdots (1 + \omega u_{n-1}).
\]

Set $x = (x_1, x_2, \ldots)$ and consider the formal product
\[
C(x) := C(x_1) C(x_2) \cdots.
\]

Arguing as in [FK2, Prop. 4.2], we see that the relation $C(x_i) C(x_j) = C(x_j) C(x_i)$ holds for all indices $i$ and $j$. We deduce that the functions $F_w(x)$ in the formal power series expansion
\[
C(x) = \sum_{w \in B_n} F_w(x) u_w
\]
are symmetric functions in $x$. The $F_w$ are the type $C$ Stanley symmetric functions, introduced and studied in [BH, FK2, L].

Let $y = (y_1, y_2, \ldots)$. The Billey-Haiman type $C$ Schubert polynomials $\mathfrak{C}_w(x; y)$ for $w \in B_n$ are defined by expanding the formal product
\[
C(x) A_1(y_1) A_2(y_2) \cdots A_{n-1}(y_{n-1}) = \sum_{w \in B_n} \mathfrak{C}_w(x; y) u_w.
\]

The above definition is equivalent to the one in [BH], as is shown in [FK2, §7]. One checks that $\mathfrak{C}_w$ is stable under the natural inclusion of $B_n$ in $B_{n+1}$, and hence well defined for $w \in B_\infty$. We also deduce the following result from (54) and (55).

**Proposition 3.** Let $w \in B_\infty$ and $x' = (x'_1, x'_2, \ldots)$. Then we have
\[
F_w(x, x') = \sum_{uv = w} F_u(x) F_v(x')
\]
and
\[
\mathfrak{C}_w(x, x'; y) = \sum_{uv = w} F_u(x) \mathfrak{C}_v(x'; y)
\]
where the sums are over all reduced factorizations $uv = w$ in $B_\infty$.

**6.2.** We say that an element $w \in B_\infty$ is $k$-Grassmannian if it is Grassmannian with respect to the simple reflection $s_k$, i.e., if $\ell(ws_i) = \ell(w) + 1$ for all $i \neq k$. Given any $k$-strict partition $\lambda$, we will define a $k$-Grassmannian element $w_\lambda \in B_\infty$.

If $\mathcal{P}(k, n)$ denotes the set of $k$-strict partitions whose Young diagrams fit inside an $(n-k) \times (n+k)$ rectangle, then $w_\lambda \in B_n$ for any $n$ such that $\lambda \in \mathcal{P}(k, n)$.

The signed permutation $w_\lambda = (w_1, \ldots, w_n)$ has a unique descent at $k$, that is, $w(i) < w(i+1)$ whenever $i \neq k$ and the first $k$ entries of $w_\lambda$ are positive. For $\lambda \in \mathcal{P}(k, n)$ we let $\lambda^1$ be the strict partition formed by the boxes of $\lambda$ in columns $k+1$ through $k+n$. The negative entries of $w_\lambda$ are then given by the parts of $\lambda^1$.

Consider the shape $\Pi(k, n)$ obtained by attaching an $(n-k) \times k$ rectangle to the left side of a staircase partition with $n$ rows. When $n = 7$ and $k = 3$, this looks as
follows.

\[ \Pi(k, n) = \]

The diagram of \( \lambda \) can be placed inside \( \Pi(k, n) \) so that the northwest corners of \( \lambda \) and \( \Pi(k, n) \) coincide. The boxes of the staircase partition which are outside \( \lambda \) then fall into south-west to north-east diagonals. The first \( k \) (respectively, the last \( n - k - \ell(\lambda^1) \)) entries of \( w_\lambda \) are the lengths of the diagonals which are (respectively, are not) \( k \)-related to one of the bottom boxes in the first \( k \) columns of \( \lambda \). For example, the partition \( \lambda = (8, 5, 2, 1) \in \mathcal{P}(3, 7) \) results in the element \( w_\lambda = 1475236 \).

Observe that \( w_\lambda \) is stable under the inclusion of \( W_n \) into \( W_{n+1} \), and thus is well defined as an element of \( W_\infty \).

Conversely, for any \( k \)-Grassmannian element \( w \in B_n \) there exist strict partitions \( u, \zeta, v \) of lengths \( k, r, \) and \( n - k - r \), respectively, so that

\[ w = (u_k, \ldots, u_1, \zeta_1, \ldots, \zeta_r, v_{n-k-r}, \ldots, v_1). \]

Define \( \alpha_i \) for \( 1 \leq i \leq k \) by

\[ \alpha_i = u_i + i - k - 1 + \# \{ j \mid \zeta_j > u_i \}. \]

Then \( w = w_\lambda \) for the partition \( \lambda \in \mathcal{P}(k, n) \) with \( \lambda^1 = \zeta \) and such that the lengths of the first \( k \) columns of \( \lambda \) are given by \( \alpha_1, \ldots, \alpha_k \).

It was proved in [BKT2, §6] that

\[ (58) \quad \Theta_\lambda(x; y) = \mathcal{C}_{w_\lambda}(x; y) \]

for any \( k \)-strict partition \( \lambda \).

6.3. The following definition can be formulated for any Coxeter group, but the name is justified by its application in the case of the finite classical Weyl groups.

**Definition 4.** An element \( w \in B_\infty \) is called **skew** if there exists a \( k \)-strict partition \( \lambda \) (for some \( k \)) and a reduced factorization \( w_\lambda = wu' \) in \( B_\infty \).

Note that if we have a reduced factorization \( w_\lambda = wu' \) in \( B_n \) for some partition \( \lambda \in \mathcal{P}(k, n) \), then the right factor \( w' \) is \( k \)-Grassmannian, and therefore equal to \( w_\mu \) for some partition \( \mu \in \mathcal{P}(k, n) \).

**Proposition 4.** Suppose that \( w \) is a skew element of \( B_\infty \), and let \( \lambda \) and \( \mu \) be \( k \)-strict partitions such that the factorization \( w_\lambda = wu_\mu \) is reduced. Then we have \( \mu \subset \lambda \) and \( F_w(x) = F_{w_\lambda/\mu}(x) \).
Proposition 4 implies that \( \mu(c) \) there exists a standard \((60)\)

\[
\text{Proof. Equation (59) may be rewritten in the form}
\]

\[
\sum_{\mu \subset \lambda} F_{\lambda/\mu}^{(k)}(x) \Theta_{\mu}(x'; y) = \Theta_{\lambda}(x, x'; y) = \sum_{w v = w_{\lambda}} F_u(x) C_v(x'; y)
\]

where the second sum is over all reduced factorizations \( w v = w_{\lambda} \). In any such factorization, the right factor \( v \) is equal to \( w_{\nu} \) for some \( k \)-strict partition \( \nu \), and therefore \( C_v(x'; y) = \Theta_{\nu}(x'; y) \). Since the \( \Theta_{\nu}(x'; y) \) for \( \nu \) a \( k \)-strict partition form a \( \mathbb{Z} \)-basis for the ring \( \Gamma^{(k)}(x'; y) \) of theta polynomials in \( x' \) and \( y \), the desired result follows immediately. \( \square \)

The Pieri rule (22) illustrates that the order relation on \( k \)-strict partitions given by the inclusion of Young diagrams is not compatible with the Bruhat order on \( B_\infty \). However, Proposition 4 shows that the weak Bruhat order on the \( k \)-Grassmannian elements of \( B_\infty \) respects the inclusion of \( k \)-strict diagrams.

**Definition 5.** Let \( \lambda \) and \( \mu \) be \( k \)-strict partitions in \( \mathcal{P}(k, n) \) with \( \mu \subset \lambda \). We say that \((\lambda, \mu)\) is a compatible pair if there is a reduced word for \( w_{\lambda} \) whose last \(|\mu|\) entries form a reduced word for \( w_{\mu} \); equivalently, if we have \( \ell(w_{\lambda}w_{\mu}^{-1}) = |\lambda - \mu| \). In other words, \((\lambda, \mu)\) is a compatible pair if \( w_{\lambda} \) exceeds \( w_{\mu} \) in the weak Bruhat order.

**Corollary 8.** Let \((\lambda, \mu)\) be a compatible pair. Then there is a 1-1 correspondence between reduced factorizations of \( w_{\lambda}w_{\mu}^{-1} \) and \( k \)-strict partitions \( \nu \) with \( \mu \subset \nu \subset \lambda \) such that \((\lambda, \nu)\) and \((\nu, \mu)\) are compatible pairs.

**Proof.** Suppose that \( w_{\lambda} = w w_{\mu} \) and let \( w = w' w'' \) be a reduced factorization. Then \( w'w_{\mu} \) is \( k \)-Grassmannian and hence equal to \( w_{\nu} \) for a unique \( k \)-strict partition \( \nu \). Proposition 4 implies that \( \mu \subset \nu \subset \lambda \), and clearly the pairs \((\lambda, \nu)\) and \((\nu, \mu)\) are compatible. The converse is obvious. \( \square \)

**Theorem 6.** Let \( \lambda \) and \( \mu \) be \( k \)-strict partitions in \( \mathcal{P}(k, n) \) with \( \mu \subset \lambda \). Then the following conditions are equivalent: (a) \( F_{\lambda/\mu}^{(k)}(x) \neq 0 \); (b) \((\lambda, \mu)\) is a compatible pair; (c) there exists a standard \( k \)-tableau on \( \lambda/\mu \). If any of these conditions holds, then \( F_{\lambda/\mu}^{(k)}(x) = F_{w_{\lambda}w_{\mu}^{-1}}(x) \).

**Proof.** Equation (59) may be rewritten in the form

\[
\sum_{\mu \subset \lambda} F_{\lambda/\mu}^{(k)}(x) \Theta_{\mu}(x'; y) = \sum_{\mu} F_{w_{\lambda}w_{\mu}^{-1}}(x) \Theta_{\mu}(x'; y)
\]

where the second sum is over all \( \mu \subset \lambda \) such that \((\lambda, \mu)\) is a compatible pair. It follows that

\[
F_{\lambda/\mu}^{(k)}(x) = \begin{cases} F_{w_{\lambda}w_{\mu}^{-1}}(x) & \text{if } (\lambda, \mu) \text{ is a compatible pair}, \\ 0 & \text{otherwise} \end{cases}
\]

and hence that (a) and (b) are equivalent. Suppose now that \((\lambda, \mu)\) is a compatible pair with \(|\lambda| = |\mu| + 1\), so that \( w_{\lambda} = s_i w_{\mu} \) for some \( i \geq 0 \). Observe that if \( x \) is a single variable, then \( F_{s_i}(x) = 2x \), and therefore \( F_{\lambda/\mu}^{(k)}(x) = 2x \neq 0 \). We deduce from Example 8(d) that \( \lambda/\mu \) must be a \( k \)-horizontal strip. Using Corollary 8, it follows that there is a 1-1 correspondence between reduced words for \( w_{\lambda}w_{\mu}^{-1} \) and sequences of \( k \)-strict partitions

\[
\mu = \lambda^0 \subset \lambda^1 \subset \cdots \subset \lambda^r = \lambda
\]
such that $|\lambda^i| = |\lambda^{i-1}| + 1$ and $\lambda^i/\lambda^{i-1}$ is a $k$-horizontal strip for $1 \leq i \leq r = |\lambda - \mu|$. The latter objects are exactly the standard $k$-tableaux on $\lambda/\mu$. This shows that (b) implies (c), and the converse is also clear. 

The previous results show that the non-zero terms in equations (49) and (51) correspond exactly to the terms in equations (57) and (56), respectively, when $w = w_\lambda$ is a $k$-Grassmannian element of $B_\infty$.

**Corollary 9.** Let $w \in B_\infty$ be a skew element and $(\lambda, \mu)$ be a compatible pair such that $w_\lambda = w w_\mu$. Then the number of reduced words for $w$ is equal to the number of standard $k$-tableaux on $\lambda/\mu$ and to the coefficient of $x_1 x_2 \cdots x_r$ in $2^{-r} F_{\lambda/\mu}^{(k)}(x)$, where $r = |\lambda - \mu| = \ell(w)$.

**Example 9.** Let $\lambda$ be a $k$-strict partition, $\lambda^1$ be defined as in §6.2, $\lambda^2 = \lambda \setminus \lambda^1$, and $\mu \subset \lambda^2$. We can form a standard $k$-tableau on $\lambda/\mu$ by filling the boxes of $\lambda^2/\mu$, going down the columns from left to right, and then filling the boxes of $\lambda^1$, going across the rows from top to bottom. If $\mu \subset \lambda$ but $\mu_1 > k$, this procedure does not always work, see for instance Example 8(c). When $k = 3$, $\lambda = (8, 6, 5, 2)$, and $\mu = \emptyset$, the $3$-tableau on $\lambda$ which results is

\[
\begin{array}{ccccccccccc}
1 & 5 & 9 & 12 & 13 & 14 & 15 & 16 \\
2 & 6 & 10 & 17 & 18 & 19 \\
3 & 7 & 11 & 20 & 21 \\
4 & 8
\end{array}
\]

which corresponds to the reduced word

$s_1 s_0 s_2 s_1 s_0 s_1 s_0 s_0 s_0 s_1 s_0 s_1 s_3 s_4 s_3 s_2 s_1 s_0 s_0 s_1 s_4 s_4 s_2 s_4 s_5 s_4 s_3$

for the Grassmannian element $w_\lambda = 1675324 \in B_7$.

A sequence $(i_1, \ldots, i_m)$ is called unimodal if for some $r$ with $0 \leq r \leq m$, we have $i_1 > i_2 > \cdots > i_r < i_{r+1} < \cdots < i_m$. An element $w \in B_\infty$ is unimodal if it has a reduced word $s_{i_1} \cdots s_{i_m}$ such that $(i_1, \ldots, i_m)$ is a unimodal sequence. A tableau $T$ has content given by the composition $\alpha$ if $\alpha_i$ of the entries of $T$ are equal to $i$, for each $i \geq 1$. We can now state the following generalization of Corollary 9.

**Proposition 5.** Let $w \in B_\infty$ be a skew element and $(\lambda, \mu)$ be a compatible pair such that $w_\lambda = w w_\mu$. Then there is a 1-1 correspondence between reduced factorizations $u_1 \cdots u_r$ of $w$ into unimodal elements $u_i$ and $k$-tableaux $T$ of shape $\lambda/\mu$ with $r$ distinct entries. The lengths of the $u_i$ agree with the content of $T$, and the number of reduced words for $w$ obtained by concatenating unimodal reduced words for $u_1, \ldots, u_r$ of the corresponding lengths is equal to $2^{\ell(T)-r}$.

**Proof.** From the definition of $F_w$ in §6.1 it follows that if there is only one variable $x$ and $w \neq 1$, then we have $F_w(x) = 2 n_w x^{\ell(w)}$, where $n_w$ denotes the number of unimodal reduced words for $w$. Moreover, for each $m \geq 1$ we have

\[
F_w(x_1, \ldots, x_m) = \sum_{u_1 \cdots u_m = w} F_{u_1}(x_1) \cdots F_{u_m}(x_m)
\]

summed over all reduced factorizations $u_1 \cdots u_m$ for $w$. The result follows by comparing (61) with Definition 3 and using Example 8(d) and Corollary 8. 

\[\square\]
Let \( \lambda \in \mathcal{P}(k, n) \) and \( w_\lambda \in B_n \) be the corresponding \( k \)-Grassmannian element. There are analogues of Corollary 9 and Proposition 5 for \( \Theta_\lambda(x; y) \) and the \( k \)-bitableaux of shape \( \lambda \). We say that a permutation \( v \in S_n \) is decreasing if \( v \) has a reduced word \( s_{i_1} \cdots s_{i_m} \) such that \( i_1 > \cdots > i_m \). Then the \( k \)-bitableaux of shape \( \lambda \) correspond to reduced factorizations \( u_1 \cdots u_r v_1 \cdots v_s \) of \( w_\lambda \) with the \( u_i \in B_n \) unimodal and the \( v_j \in S_n \) decreasing. We leave the details to the reader.

According to [BH] and [L], the type C Stanley symmetric function \( F_w \) is a nonnegative integer linear combination of Schur \( Q \)-functions. Together with Theorem 6, this implies the following result.

**Corollary 10.** For any two \( k \)-strict partitions \( \lambda, \mu \) with \( \mu \subset \lambda \), the function \( F_{\lambda/\mu}(x) \) is a nonnegative integer linear combination of Schur \( Q \)-functions.

6.4. We say that a permutation \( \varpi \) is fully commutative if any reduced word for \( \varpi \) can be obtained from any other by a sequence of braid relations that only involve commuting generators. It follows from [Ste, Thm. 4.2] that a permutation \( \varpi \) is fully commutative if and only if there exists a Grassmannian permutation \( \varpi_\lambda \) and a reduced factorization \( \varpi_\lambda = \varpi \varpi' \) for some permutation \( \varpi' \). In other words, the skew elements of the symmetric group are exactly the fully commutative elements.

Following [FS], the expansion of the formal product

\[
A_1(x_1)A_1(x_2) \cdots = \sum_{\varpi \in S_n} G_\varpi(x) u_\varpi
\]

may be used to define the type A Stanley symmetric functions \( G_\varpi(x) \) for \( \varpi \in S_n \). Stanley [Sta] introduced \( G_\varpi \) to study the set of reduced words for \( \varpi \) (he actually worked with \( G_{\varpi^{-1}} \)). It is shown in [BJS, §2] that if \( \varpi \in S_n \) is fully commutative (or equivalently, \( 321 \)-avoiding) then \( G_\varpi = s_{\lambda/\mu} \) is a skew Schur function, and the number of reduced words for \( \varpi \) is equal to the number of standard tableaux on \( \lambda/\mu \). Our present definition and study of skew elements in the hyperoctahedral group is therefore completely analogous to this established theory for the symmetric group.

Any fully commutative element of \( B_n \), in the sense of [Ste], is a skew element. However the converse is emphatically false, for example the 1-Grassmannian element \( u_{(4,1)} = 231 \) is not fully commutative. The three reduced words

\[
s_1 s_2 s_1 s_0 s_1 \quad s_2 s_1 s_2 s_0 s_1 \quad s_2 s_1 s_0 s_2 s_1
\]

for \( 231 \) correspond respectively to the three standard 1-tableaux

\[
\begin{array}{ccc}
1234 & 1245 & 1345 \\
5 & 3 & 2
\end{array}
\]

on the diagram \( \lambda = (4, 1) \).
